Petitioner respectfully moves for immediate dismissal of Application PLNG2021-006 based on fundamental procedural violations that rendered the June 20, 2025 hearing legally defective and incapable of supporting any lawful decision.

# I. THRESHOLD LEGAL VIOLATION REQUIRING DISMISSAL

## The Core Procedural Violation

The hearing record contains an irreconcilable contradiction about fundamental environmental determinations that no lawful decision can resolve:

**Official Environmental Finding (Final EIS & Staff Report):** "significant unavoidable adverse impacts"

**Undisclosed Errata Sheet:** "minor impacts" (introduced evening before or morning of hearing)

**Legal Authority Violated:** RCW 43.21C.030; WAC 197-11-600; WAC 197-11-560(1)

### A. Unauthorized Environmental Document Revisiond

**The Core Legal Violation:** CalPortland's lawyer said city staff revised Final Environmental Impact Statement conclusions from "significant unavoidable adverse impacts" to "minor impacts" via an undisclosed errata sheet submitted the evening before or the morning of the hearing, without SEPA-required public process.

**TRANSCRIPT OF CORE LEGAL VIOLATION:**

(**TIME STAMP 2:41:51**) **CalPortland:** we do anticipate a chance to respond to some of the information that we received in the PowerPoint and the errata sheet to this from the city that we're just digesting…

**(TIME STAMP: 35:01-35:18 second City of DuPont YouTube hearing upload) CalPortland's lawyer:** "I'd like to uh direct your attention to the errata sheet that was made part of the record last night or early this morning by the city and if you go to page two and three of that sheet. It indicates um uh an assessment of potential impacts to off-site water bodies including Pond Lake wetlands 8 9 10 and 11 Old Fort Lake and wetland ID 1D do you see that?" "The determination there that's been added in the errata sheet is that those impacts would be minor, is that right" To which, John Small, testifying for CalPortland replied, "I would say that minor is a correct and or apt conclusion."

**Specific Legal Authority Violated:**

- **RCW 43.21C.030** - SEPA procedural requirements for environmental document revision
- **WAC 197-11-600** - Public participation requirements for EIS amendments
- **DuPont Municipal Code** - Public notice requirements for material permit modifications

**Timeline of Procedural Violation:**

- **Weeks Prior:** Public reviewed and commented based on "significant unavoidable adverse impacts" in the Final EIS and the city's Staff Report and Recommendation
- **Evening Before or Morning of Hearing (Timestamp 17:22-19:40):** Undisclosed errata sheet introduced without disclosure of material changes
- **During Hearing:** CalPortland's attorney reveals errata sheet "made part of the record last night or early this morning"

**B. Due Process Violations**

**Constitutional Issue:** The public was denied meaningful participation by commenting for weeks on environmental findings of "significant unavoidable adverse impacts" while the city revised those conclusions to "minor impacts" via an undisclosed errata sheet added the evening of or the morning of the hearing, without providing notice or opportunity for public response as required by SEPA.

**Specific Violations:**

- **14th Amendment Due Process** - Material changes without notice
- **RCW 42.30.030** - Open Public Meetings Act violations
- **SEPA Public Participation Requirements** - WAC 197-11-340

**C. Administrative Law Violations**

**Legal Impossibility:** The hearing record contains irreconcilable contradictions about fundamental environmental conclusions that cannot support any lawful decision.

**Which Environmental Finding Governs:**

1. Staff Report: "significant unavoidable adverse impacts"
2. Undisclosed Errata Sheet: "minor impacts"
3. City Expert Testimony: Claim inability to comment on calculated impacts

## D. Record Integrity Issues

Which version is legally operative?

- Staff's formal presentation of "significant unavoidable impacts"?
- The undisclosed errata sheet claiming "minor impacts"?
- CalPortland expert testimony denying functional changes?

A hearing record cannot contain irreconcilable contradictions about fundamental environmental conclusions.

### The Fundamental Questions:

1. **Legal Authority:** Did staff have authority to substantively revise EIS conclusions via evening prior to or morning-of-hearing undisclosed errata sheet without SEPA process?
2. **Due Process:** How can material environmental conclusions be changed without public notice and comment opportunity?
3. **Expert Credibility:** How can experts claim under oath that they cannot comment on impacts they calculated in the Final EIS?
4. **Procedural Integrity:** Can conditional approval be based on undisclosed documents not available for public review?
5. **SEPA Compliance:** How can expert testimony contradict the Final EIS that represents the city's official environmental conclusions? Under **Citizens for Mount Vernon v. Mount Vernon**, 133 Wn.2d 861 (1997), environmental determinations cannot be revised without proper SEPA process. Expert testimony contradicting the Final EIS violates **WAC 197-11-560(1)**, which establishes the Final EIS as 'the agency's conclusion about significant environmental impacts.
6. **Ultra Vires Authority:** Did city staff exceed their statutory authority under **WAC 197-11-560** by unilaterally revising Final EIS conclusions without the required environmental review process?

## I. FORMAL STAFF PRESENTATION - DOCUMENTED ADMISSIONS OF CODE VIOLATIONS

During the city's formal presentation, staff made specific, documented admissions about environmental damage AND code violations that directly contradict later sworn testimony.

**DMC 25.105.050's "no net loss" requirement.** Staff formally admits the creek restoration plan - their primary mitigation strategy - **"would likely not mitigate these impacts to off-site wetlands",** making "no net loss" impossible to achieve.

**Comprehensive Plan Violation Admission (Timestamp 50:09-50:22):** Staff formally concluded: *"the significant unavoidable impacts to the impacted off-site surface waters* ***which would likely not be mitigated through the implementation of the restoration plan*** *is without mitigation* ***not in alignment with the comp plan policies*** *for protection of the long-term integrity of the national environment"*

## STAFF REPORT DOCUMENTATION OF SAME "SIGNIFICANT UNAVOIDABLE ADVERSE IMPACTS":

**Staff Report Page 11:** *"However,* ***no mitigation is provided for the significant unavoidable impacts*** *to the surface water bodies located to the south of Sequalitchew Creek (Wetland 1D; Pond Lake; Wetland#8, #9, #10, and #11; and Old Fort Lake). While the EIS finds that the natural seasonal fluctuations in water levels may make it difficult to observe changes to these water bodies,* ***these impacts do not align with Comprehensive Plan policies*** *for protection of the long-term integrity of the natural environment."*

## FINAL EIS IDENTICAL CONCLUSIONS:

**EIS Page 3.4-29:** *"Water levels in isolated lakes and kettle wetlands not directly connected by surface water to the Sequalitchew Creek system would be lowered due to lowered groundwater levels from the Proposed Action. The anticipated decrease in water levels would be approximately 3 ft for Wetland 1D; 2 ft for Pond Lake; 1 ft for Wetlands, #8, #9, #10, and #11; and 0.5 ft for Old Fort Lake.* ***Implementation of the Restoration Plan would likely not mitigate these impacts."***

**Groundwater Impacts (Timestamp 47:15-47:35):** Staff stated: *"The Vashon aquifer water table would significantly decrease in the vicinity of the south parcel groundwater discharge in the Sequalitchew Creek ravine is expected to significantly decrease"*

**Creek Flow Destruction (Timestamp 48:37-48:50):** Staff stated: *"flows in the ravine section of Sequalitchew Creek so the slopes would likely be lower than under existing conditions an estimated 10% of the time due the reduction in groundwater seeps and spring discharges to the creek following groundwater lowering this would have adverse effects on aquatic habitat"*

**Critical Legal Conclusion (Timestamp 50:09-50:22):** Staff concluded: *"the significant unavoidable impacts to the impacted off-site surface waters which would likely not be mitigated through the implementation of the restoration plan is without mitigation not in alignment with the comp plan policies"*

**Staff's Own Legal Finding:** The city's own staff report clearly states the project doesn't align with comprehensive plan policies LU-3.6, LU-10, and LU-10.2 for the protection of the long-term integrity of the natural environment.

## II. CONTRADICTORY SWORN TESTIMONY - SYSTEMATIC QUESTIONABLE STATEMENTS UNDER OATH

**Ben Lee's (City Water Consultant) Questionable Testimony About "No Net Loss" (Timestamp 2:15:30-2:17:43):** When the Hearing Examiner directly asked: *"if you're permanently reducing the water levels of a wetland is it possible then to have mitigation with those lower levels that that retains you know ecological function"*

Ben Lee gave a rambling, evasive response that avoided answering the direct question. Most damaging, when pressed further about no net loss requirements, Lee admitted under oath: *"I'm I I'm not sure if I can comment on no net loss in particular right now"*

**THE TIMELINE OF Contradictions:**

- **48:09:** Staff formally admits *"implementation of the restoration plan would likely not mitigate these impacts"*
- **1:31:05-1:31:13:** Staff presents DMC requirement for *"no net loss of stream function"*
- **1:32:03-1:32:10:** Staff discusses *"demonstration of no net loss of stream function"*
- **2:17:03:** Ben Lee claims he *"can't comment on no net loss"*

**City Expert Chris Wright's Damaging Admissions (Timestamp 32:24-34:32 second City of DuPont YouTube hearing upload):** During staff rebuttal, wetlands specialist Chris Wright was called in via Zoom and made devastating admissions under oath:

- *"we don't understand at this point what the extent of that impact is and whether or not that impact would be significant"*
- When asked if impacts could be fully mitigated: *"uh again not knowing the extent of what the impacts are I cannot say that they could be fully mitigated"* These casual dismissals directly contradict both the staff report's conclusion that impacts *"would likely not be mitigated"* and the Final EIS conclusion of "significant unavoidable adverse impacts."

**Ms. Kincaid's Questionable Testimony About Staff Conclusions (Timestamp 30:34-32:05 second City of DuPont YouTube hearing upload):** When the Hearing Examiner asked about Ms. Norris's accurate citation of unmitigated impacts in the staff report, Ms. Kincaid testified under oath: *"what we were um discussing in that report and in our analysis is that in some of these cases we don't have enough information to be able to draw a conclusion so um what what our intent is there is to say we need to have the data that we're requesting in the conditions"*

**This testimony directly contradicts:**

- **Her own staff report** which contains specific, definitive conclusions
- **Her staff's formal presentation** (timestamps 1:31:05-1:31:20) where they admitted DMC violations
- **Multiple timestamped admissions** of "significant unavoidable adverse impacts"

**Ms. Kincaid cannot claim that staff lacks sufficient information when:**

- Her own report contains explicit conclusions about environmental damage that cannot be mitigated
- Her staff formally presented DMC legal requirements during the hearing
- Multiple timestamped admissions document specific violations

## III. THE NON-DISCLOSED ERRATA SHEET

**Casual Introduction Without Disclosure (Timestamp 17:22-19:40):** Ms. Kincaid casually stated, *"there are a few more exhibits that we need to enter into the record"* without disclosing that it contained material changes to environmental conclusions.

**Critical Omission:** Ms. Kincaid failed to disclose that the errata sheet contained material changes to environmental conclusions, **downgrading impacts from "significant unavoidable" to "minor."**

**Strategic Introduction of Expert Witness (Timestamp 35:01-36:43 second City of DuPont YouTube video):**

CalPortland's attorney Steve strategically called John Small as their witness, establishing his credentials: *"I'm an environmental consultant i've got 24 years of experience with Anker QA... i have a bachelor's degree in geology and a master's in landscape architecture."* When asked about his role in the project, Small testified: *"i've been involved in the wetland assessments the impacts on fisheries plants and animals and* ***I led both those technical documents"*** - establishing him as the lead author of the very Final EIS that found "significant unavoidable adverse impacts."

**Direct Reference to Undisclosed Errata Sheet (Timestamp 36:03-36:43 second City of DuPont YouTube video):**

Steve then immediately directed Small's attention to the undisclosed document: *"i'd like to uh direct your attention to the* ***errata sheet that was made part of the record last night or early this morning by the city*** *and if you go to page two two and three of that sheet."*

**Specific Offsite Wetlands Identification (Timestamp 36:14-36:43 second City of DuPont YouTube video):**

Steve specifically identified the affected water bodies: *"it indicates um uh an assessment of potential impacts to* ***off-site water bodies including Pond Lake wetlands 8 9 10 and 11 Old Fort Lake and wetland ID 1D*** *do you see that"* Small confirmed: *"yes I do."*

**The Devastating Environmental Contradiction (Timestamp 36:35-36:43) second City of DuPont YouTube video:**

**Steve then revealed the core violation: *"okay okay and the determination there that's been added in the errata sheet is that those impacts would be minor is that right"* Small endorsed this revision: *"yes"* and further testified: *"yeah I would say that minor is a correct and or apt conclusion."***

**John Small's Dismissive "Solutions" for Unmitigatable Wetland Damage**

**Timestamp 39:02-40:32** - When the Hearing Examiner asked what would happen if there was significant decrease in wetland function contrary to expectations and how it could be mitigated:

**Solution #1: "Just Replant Different Plants"**

**John Small's Response (Timestamp 39:27-39:59):**

"either the conditions within the wetland could change without really affecting the size of the wetland and we would probably try to mitigate that... the best mitigation for those functions would

be to look at the existing vegetation and **if it's no longer supported by the hydrology uh replace it with wetland vegetation that is better able to handle that hydrology** uh it could be a conversion from emergent vegetation to shrub scrub wetland vegetation but it would remain a wetland"

**Solution #2: "Make the Replacement Wetland Bigger"**

**John Small's Response (Timestamp 40:06-40:20):**

**"if the wetlands decrease in size then we have the ability to enlarge the wetland mitigation site in the mine to accommodate any losses there"**

**Hearing Examiner Follow-up (Timestamp 40:20-40:32):**

"if you have a lowering of the wetland you know the boundary changes that be associated with the reduction in the size and you're saying you would compensate for that by the compensation wetland then is"

**John Small: "Yeah that would most likely be mitigated at a 2 to 1 ratio under the code"**

**How can John Small testify under oath that environmental impacts are "minor" when the Final EIS - the legally binding SEPA document that underwent formal public process - concluded they are "significant unavoidable adverse impacts."?** His testimony directly contradicts the official environmental determination and violates the integrity of the SEPA process.

**Pattern of Last-Minute Document Changes**

Miss Klein also admitted to adding new content, stating: *"anything you see in yellow is a new addition to the staff to the staff report"* regarding dust control analysis that was "erroneously overseen" in the original report.

**This reveals a pattern of:**

- Material changes made to environmental documents at the last minute
- Seeming coordination between city staff and applicant
- Substantial revisions not disclosed to public until the end of the hearing
- Environmental conclusions changed in real-time without public process

**Legal Questions:**

1. **Authority:** Did staff have legal authority to substantively revise EIS conclusions via errata sheet without SEPA process?
2. **Notice:** How can material environmental conclusions be changed without public notice and comment opportunity?
3. **Timing:** Can conditional approval be based on undisclosed documents unavailable for public review?

## IV. UNANSWERABLE LEGAL QUESTIONS MANDATING DISMISSAL

The hearing record presents fundamental legal questions that cannot be resolved without dismissing this proceeding:

1. **SEPA Compliance:** How can expert testimony contradict the Final EIS that represents the city's official environmental conclusions under RCW 43.21C?
2. **Administrative Authority:** What legal authority permitted staff to unilaterally reverse environmental conclusions through an evening before or morning-of-hearing errata sheet without required public process?
3. **Due Process:** How can the public meaningfully participate when material environmental findings are revised without public notice?
4. **Record Integrity:** Which contradictory version of environmental impacts should govern the decision when the record contains irreconcilable contradictions?
5. **Expert Credibility:** How can experts claim under oath their inability to comment on impacts they calculated in the Final EIS?

## V. SILENCE AS ADMISSION: CITY'S FAILURE TO DISPUTE CALPORTLAND'S CLAIMS THAT THE UNDISCLOSED ERRATA CHANGED THE DAMAGES TO MINOR

Most troubling, when CalPortland's attorney stated that the city's errata sheet determined 'those impacts would be minor,' city staff offered no correction or clarification. In a legal proceeding, silence in the face of material factual claims constitutes admission. The presence of city legal counsel throughout these proceedings makes the violations inexcusable. The city cannot claim procedural ignorance when its own legal counsel witnessed every violation documented above and chose not to intervene.

## VI. REQUESTED RELIEF

The documented procedural violations and systematic contradictions require:

**Immediate Relief: Dismissal** of application due to fundamentally corrupted hearing process

**Additional relief requested:**

1. **Errata Sheet Authority Review:** Determine legal authority under WAC 197-11-560 for substantive revision of Final EIS conclusions via morning-of-hearing errata sheet
2. **Ex Parte Investigation:** Investigate apparent coordination between city staff and applicant regarding advance disclosure of errata sheet contents

**The undisclosed errata sheet represents a fundamental violation of SEPA's public participation requirements.** The public spent weeks commenting on environmental conclusions of 'significant unavoidable adverse impacts' while an undisclosed document apparently reached opposite conclusions. This bait-and-switch tactic denied meaningful public participation and violated

constitutional due process. Any decision based on undisclosed environmental document revisions without required public notice and comment is void ab initio under SEPA and administrative law.

# VI. LEGAL CONCLUSION

The hearing examiner heard CalPortland's attorney state that the city's errata sheet changed environmental impacts to 'minor,' heard no correction from city staff, yet has a record showing 'significant unavoidable adverse impacts.' This creates an irreconcilable contradiction that no lawful decision can be based upon.

The hearing process has lost all legal credibility through systematic procedural violations, undisclosed document revisions, and contradictory sworn testimony. These are not disagreements about environmental science—they are fundamental violations of administrative law, SEPA requirements, and constitutional due process.

**Most troubling, when CalPortland's attorney stated that the city's errata sheet determined 'those impacts would be minor,' city staff offered no correction or clarification. City legal counsel was present during this exchange.** In a legal proceeding, silence in the face of material factual claims constitutes admission. This allows CalPortland's characterization that environmental findings were changed from "significant unavoidable adverse impacts" to "minor impacts" to remain part of the unchallenged hearing record.

**No lawful approval can be issued based on a hearing record containing:**

- **Undisclosed environmental document revisions** without required public process
- **Sworn testimony by the Planning Director inconsistent with her own report**
- **Expert witnesses unable to comment on impacts they previously calculated**
- **Irreconcilable contradictions** about fundamental environmental conclusions
- **City legal counsel present during systematic procedural violations without intervention**

Under **Citizens for Mount Vernon v. Mount Vernon**, 133 Wn.2d 861 (1997), environmental determinations cannot be revised without proper SEPA process. The undisclosed errata sheet represents a fundamental violation of SEPA's public participation requirements and constitutional due process.

**Dismissal is the only legally available remedy for this corrupted proceeding.**

These documented violations make approval legally impossible under Washington environmental law. Dismissal is the only option.

Respectfully submitted,

Judy Norris

**Subject:** Procedural Issues Identified in CalPortland Hearing Record

**Subject: Procedural Issues Identified in CalPortland Hearing Record**

Dear Ron, Barb, and Gordon,

I am writing to give you advance notice that I have identified significant procedural issues in the June 20, 2025 CalPortland hearing that I will be documenting in my formal comments to the hearing examiner.

**Key Issues Identified:**

1. **Material contradictions** between staff's formal presentation (detailed environmental damage calculations) and subsequent sworn testimony (claims of ignorance about the same impacts)
2. **Last-minute errata sheet** that appears to have downgraded impacts from "significant unavoidable" to "minor" - added the morning of the hearing without public notice or comment opportunity
3. **Potential SEPA violations** regarding substantive changes to environmental conclusions outside proper public process
4. **Due process concerns** about material changes to the decision record made without adequate public participation

I have documented these issues with specific timestamps from the hearing transcript and will be submitting detailed analysis to the hearing examiner by the Wednesday deadline.

I wanted to give you advance notice so you can review the procedural record and consider whether additional legal consultation may be appropriate before the hearing examiner issues a decision.

The issues identified appear to go beyond typical hearing disagreements and raise questions about compliance with municipal code, SEPA, and administrative law requirements.

Respectfully,
Judy Norris
1485 Kittson Street
DuPont, WA 98327

**Subject:** Subject: EMERGENCY MOTION TO DISMISS - CalPortland Mine Expansion (PLNG2021-006)- SEPA Violations
**Attachments:** Motion to Dismiss CalPortland South Parcel Mine Expansion (PLNG2021-006) June 23, 2025 .pdf

Dear Mr. Olbrechts:

I am submitting the attached **Emergency Motion to Dismiss** regarding systematic legal violations documented in the June 20, 2025 hearing record for the CalPortland South Parcel Mine Expansion (PLNG2021-006).

**DOCUMENT:** EMERGENCY MOTION TO DISMISS - Systematic SEPA Violations and Corrupted Hearing Record

**REQUESTED IMMEDIATE RELIEF:** DISMISSAL of application due to fundamentally corrupted hearing process that cannot support any lawful decision.

**THRESHOLD LEGAL VIOLATION:**

The hearing record contains an irreconcilable contradiction about fundamental environmental determinations that renders any lawful decision impossible:

• **Official Environmental Finding:** "significant unavoidable adverse impacts" (Final EIS & Staff Report)
• **Undisclosed Errata Sheet:** "minor impacts" (introduced evening before/morning of hearing without public process)

**KEY PROCEDURAL VIOLATIONS DOCUMENTED:**
• **Unauthorized Environmental Document Revision** - Final EIS conclusions unilaterally changed via undisclosed errata sheet without required SEPA process (WAC 197-11-600, RCW 43.21C.030)
• **Due Process Violations** - Material environmental findings revised without public notice, violating constitutional requirements and WAC 197-11-340
• **Record Integrity Failure** - Irreconcilable contradictions between official environmental determinations make any decision legally impossible
• **Silent Admission** - City staff failed to correct CalPortland's characterization of errata sheet changes despite legal counsel present

**EVIDENCE BASIS:**

All allegations supported by exact timestamps from official hearing transcript, including CalPortland counsel's admission that errata sheet was "made part of the record last night or early this morning" (Timestamp 35:01-35:18).

**LEGAL STANDARD:**
Under *Citizens for Mount Vernon v. Mount Vernon*, 133 Wn.2d 861 (1997), environmental determinations cannot be revised without proper SEPA process. The systematic procedural violations documented render this proceeding legally defective beyond remedy.

**DISMISSAL IS THE ONLY LEGALLY AVAILABLE REMEDY.**
These threshold legal violations must be resolved before any substantive decision, as the corrupted hearing record makes any approval void *ab initio* under Washington environmental law.

I respectfully request immediate consideration of this Emergency Motion to Dismiss.

**Respectfully submitted,**
Judy Norris

**DATE:** June 23, 2025

**RE: CalPortland South Parcel Mine Expansion - PLNG2021-006**
**URGENT: MOTION TO DISMISS: Systematic SEPA Violations and Corrupted Hearing Record**

# URGENT REQUEST FOR IMMEDIATE DISMISSAL

Petitioner respectfully moves for immediate dismissal of Application PLNG2021-006 based on fundamental procedural violations that rendered the June 20, 2025 hearing legally defective and incapable of supporting any lawful decision.

# I. THRESHOLD LEGAL VIOLATION REQUIRING DISMISSAL

## The Core Procedural Violation

The hearing record contains an irreconcilable contradiction about fundamental environmental determinations that no lawful decision can resolve:

**Official Environmental Finding (Final EIS & Staff Report):** "significant unavoidable adverse impacts"

**Undisclosed Errata Sheet:** "minor impacts" (introduced evening before or morning of hearing)

**Legal Authority Violated:** RCW 43.21C.030; WAC 197-11-600; WAC 197-11-560(1)

### A. Unauthorized Environmental Document Revisiond

**The Core Legal Violation:** CalPortland's lawyer said city staff revised Final Environmental Impact Statement conclusions from "significant unavoidable adverse impacts" to "minor impacts" via an undisclosed errata sheet submitted the evening before or the morning of the hearing, without SEPA-required public process.

**TRANSCRIPT OF CORE LEGAL VIOLATION:**

(**TIME STAMP 2:41:51**) **CalPortland:** we do anticipate a chance to respond **t**o some of the information that we received in the PowerPoint and the errata sheet to this from the city that we're just digesting…

**(TIME STAMP: 35:01-35:18 second City of DuPont YouTube hearing upload) CalPortland's lawyer:** "I'd like to uh direct your attention to the **e**rrata sheet that was made part of the record last night or early this morning by the cit**y** and if you go to page two and three of that sheet. It indicates um uh an assessment of potential impacts to off-site water bodies including Pond Lake wetlands 8 9 10 and 11 Old Fort Lake and wetland ID 1D do you see that?" "The determination there that's been added in the errata sheet is that those impacts would be minor**,** is that right" To which, John Small, testifying for CalPortland replied, "I would say that minor is a correct and or apt conclusion."

**Specific Legal Authority Violated:**

- **RCW 43.21C.030** - SEPA procedural requirements for environmental document revision
- **WAC 197-11-600** - Public participation requirements for EIS amendments
- **DuPont Municipal Code** - Public notice requirements for material permit modifications

**Timeline of Procedural Violation:**

- **Weeks Prior:** Public reviewed and commented based on "significant unavoidable adverse impacts" in the Final EIS and the city's Staff Report and Recommendation
- **Evening Before or Morning of Hearing (Timestamp 17:22-19:40):** Undisclosed errata sheet introduced without disclosure of material changes
- **During Hearing:** CalPortland's attorney reveals errata sheet "made part of the record last night or early this morning"

**B. Due Process Violations**

**Constitutional Issue:** The public was denied meaningful participation by commenting for weeks on environmental findings of "significant unavoidable adverse impacts" while the city revised those conclusions to "minor impacts" via an undisclosed errata sheet added the evening of or the morning of the hearing, without providing notice or opportunity for public response as required by SEPA.

**Specific Violations:**

- **14th Amendment Due Process** - Material changes without notice
- **RCW 42.30.030** - Open Public Meetings Act violations
- **SEPA Public Participation Requirements** - WAC 197-11-340

**C. Administrative Law Violations**

**Legal Impossibility:** The hearing record contains irreconcilable contradictions about fundamental environmental conclusions that cannot support any lawful decision.

**Which Environmental Finding Governs:**

1. Staff Report: "significant unavoidable adverse impacts"
2. Undisclosed Errata Sheet: "minor impacts"
3. City Expert Testimony: Claim inability to comment on calculated impacts

**D. Record Integrity Issues**

Which version is legally operative?

- Staff's formal presentation of "significant unavoidable impacts"?
- The undisclosed errata sheet claiming "minor impacts"?
- CalPortland expert testimony denying functional changes?

A hearing record cannot contain irreconcilable contradictions about fundamental environmental conclusions.

**The Fundamental Questions:**

1. **Legal Authority:** Did staff have authority to substantively revise EIS conclusions via evening prior to or morning-of-hearing undisclosed errata sheet without SEPA process?
2. **Due Process:** How can material environmental conclusions be changed without public notice and comment opportunity?
3. **Expert Credibility:** How can experts claim under oath that they cannot comment on impacts they calculated in the Final EIS?
4. **Procedural Integrity:** Can conditional approval be based on undisclosed documents not available for public review?
5. **SEPA Compliance:** How can expert testimony contradict the Final EIS that represents the city's official environmental conclusions? Under **Citizens for Mount Vernon v. Mount Vernon**, 133 Wn.2d 861 (1997), environmental determinations cannot be revised without proper SEPA process. Expert testimony contradicting the Final EIS violates **WAC 197-11-560(1)**, which establishes the Final EIS as 'the agency's conclusion about significant environmental impacts.
6. **Ultra Vires Authority:** Did city staff exceed their statutory authority under **WAC 197-11-560** by unilaterally revising Final EIS conclusions without the required environmental review process?

## I. FORMAL STAFF PRESENTATION - DOCUMENTED ADMISSIONS OF CODE VIOLATIONS

During the city's formal presentation, staff made specific, documented admissions about environmental damage AND code violations that directly contradict later sworn testimony.

**DMC 25.105.050's "no net loss" requirement.** Staff formally admits the creek restoration plan - their primary mitigation strategy - **"would likely not mitigate these impacts to off-site wetlands",** making "no net loss" impossible to achieve.

**Comprehensive Plan Violation Admission (Timestamp 50:09-50:22):** Staff formally concluded: *"the significant unavoidable impacts to the impacted off-site surface waters* ***which would likely not be mitigated through the implementation of the restoration plan*** *is without mitigation* ***not in alignment with the comp plan policies*** *for protection of the long-term integrity of the national environment"*

**STAFF REPORT DOCUMENTATION OF SAME "SIGNIFICANT UNAVOIDABLE ADVERSE IMPACTS":**

**Staff Report Page 11:** *"However,* ***no mitigation is provided for the significant unavoidable impacts*** *to the surface water bodies located to the south of Sequalitchew Creek (Wetland 1D; Pond Lake; Wetland#8, #9, #10, and #11; and Old Fort Lake). While the EIS finds that the natural seasonal fluctuations in water levels may make it difficult to observe changes to these water bodies,* ***these impacts do not align with Comprehensive Plan policies*** *for protection of the long-term integrity of the natural environment."*

**FINAL EIS IDENTICAL CONCLUSIONS:**

**EIS Page 3.4-29:** *"Water levels in isolated lakes and kettle wetlands not directly connected by surface water to the Sequalitchew Creek system would be lowered due to lowered groundwater levels from the Proposed Action. The anticipated decrease in water levels would be approximately 3 ft for Wetland 1D; 2 ft for Pond Lake; 1 ft for Wetlands, #8, #9, #10, and #11; and 0.5 ft for Old Fort Lake.* ***Implementation of the Restoration Plan would likely not mitigate these impacts."***

**Groundwater Impacts (Timestamp 47:15-47:35):** Staff stated: *"The Vashon aquifer water table would significantly decrease in the vicinity of the south parcel groundwater discharge in the Sequalitchew Creek ravine is expected to significantly decrease"*

**Creek Flow Destruction (Timestamp 48:37-48:50):** Staff stated: *"flows in the ravine section of Sequalitchew Creek so the slopes would likely be lower than under existing conditions an estimated 10% of the time due the reduction in groundwater seeps and spring discharges to the creek following groundwater lowering this would have adverse effects on aquatic habitat"*

**Critical Legal Conclusion (Timestamp 50:09-50:22):** Staff concluded: *"the significant unavoidable impacts to the impacted off-site surface waters which would likely not be mitigated through the implementation of the restoration plan is without mitigation not in alignment with the comp plan policies"*

**Staff's Own Legal Finding:** The city's own staff report clearly states the project doesn't align with comprehensive plan policies LU-3.6, LU-10, and LU-10.2 for the protection of the long-term integrity of the natural environment.

**II. CONTRADICTORY SWORN TESTIMONY - SYSTEMATIC QUESTIONABLE STATEMENTS UNDER OATH**

**Ben Lee's (City Water Consultant) Questionable Testimony About "No Net Loss" (Timestamp 2:15:30-2:17:43):** When the Hearing Examiner directly asked: *"if you're permanently reducing the water levels of a wetland is it possible then to have mitigation with those lower levels that that retains you know ecological function"*

Ben Lee gave a rambling, evasive response that avoided answering the direct question. Most damaging, when pressed further about no net loss requirements, Lee admitted under oath: *"I'm I I'm not sure if I can comment on no net loss in particular right now"*

**THE TIMELINE OF Contradictions:**

- **48:09:** Staff formally admits *"implementation of the restoration plan would likely not mitigate these impacts"*
- **1:31:05-1:31:13:** Staff presents DMC requirement for *"no net loss of stream function"*
- **1:32:03-1:32:10:** Staff discusses *"demonstration of no net loss of stream function"*
- **2:17:03:** Ben Lee claims he *"can't comment on no net loss"*

**City Expert Chris Wright's Damaging Admissions (Timestamp 32:24-34:32 second City of DuPont YouTube hearing upload):** During staff rebuttal, wetlands specialist Chris Wright was called in via Zoom and made devastating admissions under oath:

- *"we don't understand at this point what the extent of that impact is and whether or not that impact would be significant"*
- When asked if impacts could be fully mitigated: *"uh again not knowing the extent of what the impacts are I cannot say that they could be fully mitigated"* These casual dismissals directly contradict both the staff report's conclusion that impacts *"would likely not be mitigated"* and the Final EIS conclusion of "significant unavoidable adverse impacts."

**Ms. Kincaid's Questionable Testimony About Staff Conclusions (Timestamp 30:34-32:05 second City of DuPont YouTube hearing upload):** When the Hearing Examiner asked about Ms. Norris's accurate citation of unmitigated impacts in the staff report, Ms. Kincaid testified under oath: *"what we were um discussing in that report and in our analysis is that in some of these cases we don't have enough information to be able to draw a conclusion so um what what our intent is there is to say we need to have the data that we're requesting in the conditions"*

**This testimony directly contradicts:**

- **Her own staff report** which contains specific, definitive conclusions
- **Her staff's formal presentation** (timestamps 1:31:05-1:31:20) where they admitted DMC violations
- **Multiple timestamped admissions** of "significant unavoidable adverse impacts"

**Ms. Kincaid cannot claim that staff lacks sufficient information when:**

- Her own report contains explicit conclusions about environmental damage that cannot be mitigated
- Her staff formally presented DMC legal requirements during the hearing
- Multiple timestamped admissions document specific violations

## III. THE NON-DISCLOSED ERRATA SHEET

**Casual Introduction Without Disclosure (Timestamp 17:22-19:40):** Ms. Kincaid casually stated, *"there are a few more exhibits that we need to enter into the record"* without disclosing that it contained material changes to environmental conclusions.

**Critical Omission:** Ms. Kincaid failed to disclose that the errata sheet contained material changes to environmental conclusions, **downgrading impacts from "significant unavoidable" to "minor."**

**Strategic Introduction of Expert Witness (Timestamp 35:01-36:43 second City of DuPont YouTube video):**

CalPortland's attorney Steve strategically called John Small as their witness, establishing his credentials: *"I'm an environmental consultant i've got 24 years of experience with Anker QA... i have a bachelor's degree in geology and a master's in landscape architecture."* When asked about his role in the project, Small testified: *"i've been involved in the wetland assessments the impacts on fisheries plants and animals and* ***I led both those technical documents"*** - establishing him as the lead author of the very Final EIS that found "significant unavoidable adverse impacts."

**Direct Reference to Undisclosed Errata Sheet (Timestamp 36:03-36:43 second City of DuPont YouTube video):**

Steve then immediately directed Small's attention to the undisclosed document: *"i'd like to uh direct your attention to the* ***errata sheet that was made part of the record last night or early this morning by the city*** *and if you go to page two two and three of that sheet."*

**Specific Offsite Wetlands Identification (Timestamp 36:14-36:43 second City of DuPont YouTube video):**

Steve specifically identified the affected water bodies: *"it indicates um uh an assessment of potential impacts to* ***off-site water bodies including Pond Lake wetlands 8 9 10 and 11 Old Fort Lake and wetland ID 1D*** *do you see that"* Small confirmed: *"yes I do."*

**The Devastating Environmental Contradiction (Timestamp 36:35-36:43) second City of DuPont YouTube video:**

**Steve then revealed the core violation: *"okay okay and the determination there that's been added in the errata sheet is that those impacts would be minor is that right"* Small endorsed this revision: *"yes"* and further testified: *"yeah I would say that minor is a correct and or apt conclusion."***

**John Small's Dismissive "Solutions" for Unmitigatable Wetland Damage**

**Timestamp 39:02-40:32** - When the Hearing Examiner asked what would happen if there was significant decrease in wetland function contrary to expectations and how it could be mitigated:

**Solution #1: "Just Replant Different Plants"**

**John Small's Response (Timestamp 39:27-39:59):**

"either the conditions within the wetland could change without really affecting the size of the wetland and we would probably try to mitigate that... the best mitigation for those functions would

be to look at the existing vegetation and **if it's no longer supported by the hydrology uh replace it with wetland vegetation that is better able to handle that hydrology** uh it could be a conversion from emergent vegetation to shrub scrub wetland vegetation but it would remain a wetland"

**Solution #2: "Make the Replacement Wetland Bigger"**

**John Small's Response (Timestamp 40:06-40:20):**

**"if the wetlands decrease in size then we have the ability to enlarge the wetland mitigation site in the mine to accommodate any losses there"**

**Hearing Examiner Follow-up (Timestamp 40:20-40:32):**

"if you have a lowering of the wetland you know the boundary changes that be associated with the reduction in the size and you're saying you would compensate for that by the compensation wetland then is"

**John Small: "Yeah that would most likely be mitigated at a 2 to 1 ratio under the code"**

**How can John Small testify under oath that environmental impacts are "minor" when the Final EIS - the legally binding SEPA document that underwent formal public process - concluded they are "significant unavoidable adverse impacts."?** His testimony directly contradicts the official environmental determination and violates the integrity of the SEPA process.

**Pattern of Last-Minute Document Changes**

Miss Klein also admitted to adding new content, stating: *"anything you see in yellow is a new addition to the staff to the staff report"* regarding dust control analysis that was "erroneously overseen" in the original report.

**This reveals a pattern of:**

- Material changes made to environmental documents at the last minute
- Seeming coordination between city staff and applicant
- Substantial revisions not disclosed to public until the end of the hearing
- Environmental conclusions changed in real-time without public process

**Legal Questions:**

1. **Authority:** Did staff have legal authority to substantively revise EIS conclusions via errata sheet without SEPA process?
2. **Notice:** How can material environmental conclusions be changed without public notice and comment opportunity?
3. **Timing:** Can conditional approval be based on undisclosed documents unavailable for public review?

## IV. UNANSWERABLE LEGAL QUESTIONS MANDATING DISMISSAL

The hearing record presents fundamental legal questions that cannot be resolved without dismissing this proceeding:

1. **SEPA Compliance:** How can expert testimony contradict the Final EIS that represents the city's official environmental conclusions under RCW 43.21C?
2. **Administrative Authority:** What legal authority permitted staff to unilaterally reverse environmental conclusions through an evening before or morning-of-hearing errata sheet without required public process?
3. **Due Process:** How can the public meaningfully participate when material environmental findings are revised without public notice?
4. **Record Integrity:** Which contradictory version of environmental impacts should govern the decision when the record contains irreconcilable contradictions?
5. **Expert Credibility:** How can experts claim under oath their inability to comment on impacts they calculated in the Final EIS?

## V. SILENCE AS ADMISSION: CITY'S FAILURE TO DISPUTE CALPORTLAND'S CLAIMS THAT THE UNDISCLOSED ERRATA CHANGED THE DAMAGES TO MINOR

Most troubling, when CalPortland's attorney stated that the city's errata sheet determined 'those impacts would be minor,' city staff offered no correction or clarification. In a legal proceeding, silence in the face of material factual claims constitutes admission. The presence of city legal counsel throughout these proceedings makes the violations inexcusable. The city cannot claim procedural ignorance when its own legal counsel witnessed every violation documented above and chose not to intervene.

## VI. REQUESTED RELIEF

The documented procedural violations and systematic contradictions require:

**Immediate Relief: Dismissal** of application due to fundamentally corrupted hearing process

**Additional relief requested:**

1. **Errata Sheet Authority Review:** Determine legal authority under WAC 197-11-560 for substantive revision of Final EIS conclusions via morning-of-hearing errata sheet
2. **Ex Parte Investigation:** Investigate apparent coordination between city staff and applicant regarding advance disclosure of errata sheet contents

**The undisclosed errata sheet represents a fundamental violation of SEPA's public participation requirements.** The public spent weeks commenting on environmental conclusions of 'significant unavoidable adverse impacts' while an undisclosed document apparently reached opposite conclusions. This bait-and-switch tactic denied meaningful public participation and violated

constitutional due process. Any decision based on undisclosed environmental document revisions without required public notice and comment is void ab initio under SEPA and administrative law.

# VI. LEGAL CONCLUSION

The hearing examiner heard CalPortland's attorney state that the city's errata sheet changed environmental impacts to 'minor,' heard no correction from city staff, yet has a record showing 'significant unavoidable adverse impacts.' This creates an irreconcilable contradiction that no lawful decision can be based upon.

The hearing process has lost all legal credibility through systematic procedural violations, undisclosed document revisions, and contradictory sworn testimony. These are not disagreements about environmental science—they are fundamental violations of administrative law, SEPA requirements, and constitutional due process.

**Most troubling, when CalPortland's attorney stated that the city's errata sheet determined 'those impacts would be minor,' city staff offered no correction or clarification. City legal counsel was present during this exchange.** In a legal proceeding, silence in the face of material factual claims constitutes admission. This allows CalPortland's characterization that environmental findings were changed from "significant unavoidable adverse impacts" to "minor impacts" to remain part of the unchallenged hearing record.

**No lawful approval can be issued based on a hearing record containing:**

- **Undisclosed environmental document revisions** without required public process
- **Sworn testimony by the Planning Director inconsistent with her own report**
- **Expert witnesses unable to comment on impacts they previously calculated**
- **Irreconcilable contradictions** about fundamental environmental conclusions
- **City legal counsel present during systematic procedural violations without intervention**

Under **Citizens for Mount Vernon v. Mount Vernon**, 133 Wn.2d 861 (1997), environmental determinations cannot be revised without proper SEPA process. The undisclosed errata sheet represents a fundamental violation of SEPA's public participation requirements and constitutional due process.

**Dismissal is the only legally available remedy for this corrupted proceeding.**

These documented violations make approval legally impossible under Washington environmental law. Dismissal is the only option.

Respectfully submitted,

Judy Norris

**Subject:** Letter for hearing examiner concerning SEPA violations

To the Hearing Examiner,

This is very concerning. These violations need to be addressed before any decisions are made.

City changed environmental impact findings from "significant impacts" to "minor impacts" the morning of or the night before CalPortland's mine hearing without revealing the changes to the public until the CalPortland lawyer referenced it at the end of the hearing—breaking Washington State environmental law.

The CalPortland mine hearing revealed VIOLATIONS OF STATE LAW that threaten our environmental protections:

• Bait & Switch on Environmental Damage (VIOLATES RCW 43.21C.030): City staff found "significant unavoidable adverse impacts" to our wetlands and Sequalitchew Creek, but CalPortland's lawyer revealed the city quietly changed this to "minor impacts" in an undisclosed document the night before or the morning of the hearing—ILLEGAL under Washington State Environmental Policy

• Expert Contradictions Under Oath (VIOLATES WAC 197-11-560): The city's own water consultant testified he "can't comment" on legal requirements he helped evaluate, while other experts contradicted the official environmental findings they wrote—ILLEGAL under state regulations establishing Final EIS as binding.

Why This Matters: These aren't just "procedural concerns"—they are VIOLATIONS OF WASHINGTON STATE

**Subject:** Mine expansion

Dear Ms. Kincaid:

This is the testimony I was prepared to give at the hearing 6/20/25, but I was unable to stay beyond 11:30.

I'm here today to strongly oppose the mine expansion and to state my primary concerns, which are as follows:

-It will have irreversible environmental impacts that are nothing short of devastating to DuPont citizens, future generations, and the ecosystem, which includes wildlife and their habitat.

-Our marshes will permanently lose 1-3 feet of water and the Sequalitchew Creek flow will decrease significantly as a result of dewatering the Vashon aquifer.

-188 acres of trees and foliage will be destroyed, which means a massive loss of the ecosystem and habitat for wildlife, and many will be killed in this process.

-Creekside Village and other nearby homes will be subjected to the noise and disruption of bulldozers, other heavy equipment, and logging operations for an extended period, which will impact quality of life.

-It violates city law and tribal consultation requirements.

-My home of 17 years backs up to Bell Marsh, and over the years I have enjoyed seeing and hearing the many wildlife species the marsh supports such as eagles, herons, owls, ducks, geese, deer, frogs, and more. It is heartbreaking to think that their habitat and water supply would be compromised and likely no longer be adequate. This, tragically, would be true across our marsh system.

In conclusion, it is beyond comprehension why the exploitation of DuPont's natural resources would be permitted for the benefit of a private enterprise. We

must maintain the integrity and biodiversity of our ecosystem for the benefit of current and future generations of humans and wildlife and, therefore, I urge you to deny approval of the mine expansion.

Thank you,

Lynn Okita, Bell Hill

**Subject:** Oppose Pioneer Aggregates Mine Expansion- PLNG2021-006

Dear Hearing Examiner,
I oppose the Pioneer Aggregates South Parcel Mine Expansion (PLNG2021-006).
City staff admits this project violates the Comprehensive Plan AND Critical Area Ordinance. The Staff Report states it "does not align with Comprehensive Plan policies" and admits "no mitigation is provided for the significant unavoidable impacts to the surface water bodies" - directly violating DMC 25.105.050, which REQUIRES mitigation "to achieve no net loss of stream function."
Scientists in the Final EIS admit "significant unavoidable adverse impacts" including:
• 83% creek flow loss along the Sequalitchew Creek trail from drying up natural seeps and springs
• Vashon Aquifer levels dropping 8+ feet permanently
• Multiple wetlands losing 1-3 feet of water forever
• Creek temperatures getting too hot for fish survival
• Seep wetlands along the creek ravine disrupted permanently
The EIS states the restoration plan "would likely NOT mitigate these impacts."
The Nisqually Indian Tribe never signed the 2011 Settlement Agreement that underlies this entire project. The sovereign tribal nation is formally appealing the Final EIS, citing:
• Failure to properly identify tribal cultural resources
• Violation of tribal consultation requirements
• No adequate mitigation for impacts to sacred sites
How can you approve a project without consent from the sovereign tribal nation on their ancestral lands?
The city's conditional approval requires 38 conditions to "mitigate" environmental damage that the reports already prove cannot be mitigated. You cannot require the impossible. Plus, CalPortland has had OVER 15 years to provide the mitigation requirements in the Critical Areas Ordinance.
How can you approve a project that:
• Violates city law (Comprehensive Plan AND Critical Area Ordinance)
• Requires fixing damage scientists say CANNOT be fixed?
• Demands impossible mitigation conditions?
This is legally impossible. DENY the approval.

Sincerely,

Carol Oliver

Re: Public Comment on Pioneer Aggregates South Parcel Mine Expansion Project

Date: June 24, 2025

I'm writing in opposition to the proposed gravel mine expansion in Dupont, Washington. This plan includes lowering the groundwater table in a large, important, beautiful and ecologically sensitive watershed of our Puget Sound area. It would both change water levels and pathways, and leave bodies of water physically disconnected. In addition a large number of trees would be cut down. The cumulative changes to the environment would effectively eliminate many acres of forest and marsh, disrupt salmon habitat, counter decades of salmon restoration and orca recovery efforts, and forever change the complex and magnificent ecosystem that nature has provided for us.

Besides just being wrong and harmful, these impacts violate the City of DuPont's policies, which mandate no net loss of wetland and stream functions. The mitigation efforts that are being offered are seriously inadequate to address the scope of damage being proposed by the mining company. They are offered by people and organizations that openly admit they do not have enough information or knowledge to predict what the true impact of the mining operation will be. Also importantly, they lack awareness and consideration of indigenous tribal cultural traditions and resources that would be affected.

Chris Wright, one of the city expert consultants, said in his testimony that the city has identified possible changes to the watershed that have the potential to affect offsite wetlands, and that it isn't understood at this point what the extent of that impact would be and whether it would be significant. He concluded in response to questioning that not knowing the extent of what those changes will be, he could not say that they will be fully mitigated. John Small, the consultant involved in the wetlands

assessments and the impacts on fisheries, plants, and animals, said in his testimony that there will be water loss and fluctuations, and it's unknown if there will be a significant decrease in wetland function, and if there will be periods of time when the water level is low for long enough to kill existing vegetation. He said in response to questioning that the mitigation, if that happens, would be to bring in different types of plants that would grow in the drier conditions. That this would be considered mitigation disturbs me. It doesn't seem based on a good understanding or appreciation of how ecosystems and biodiversity work.

In summary, I fear that what the Pioneer Aggregates Gravel Mine is proposing would compromise our watershed, perhaps beyond repair, and threaten the long term health of this amazing natural environment. The studies and the mitigation plan offered do not do justice to the complexity and value of nature in its totality. We have the chance to save the last remaining forest area of Sequalitchew Creek. Please do not allow the destruction of this unique natural resource. Protect our water, our forests, our wetlands, and the wildlife that is part of its web of life, including salmon, orcas, western gray squirrels, bats and birds. Reject this proposal.

Thank you for the chance to offer public comment. Please enter these comments into the record.

**Subject:** LETTER FOR HEARING ESXAMINER CONCERNING SEPA VIOLATIONS

It has been brought to my attention that there have been violations of state law that threaten our DuPont environmental protections. Apparently, the City of DoPnt secretly changed environmental impact findings from "significant damage" to "minor impacts" the night before CalPortland's mine hearing without revealing the changes to the public until the CalPortland lawyer referenced it at the end of the hearing. This broke Washington State environmental law. This violates RCW 43.21C.030. WAC 197-11-560 was also violated when Dupont's own water consultant testified he "can't comment' on legal requirements he helped evaluate, while other experts contradicted the official environmental findings they wrote.This is illegal under state regulations establishing Final EIS as binding.

I demand these procedural violations be addressed before any decision is made. These aren't just procedural concerns, they are violations of Washington state law.

DuPont Hearing Examiner
303 Barksdale Avenue
DuPont, Washington
98327

Subject: Pioneer Aggregate-Glacier Northwest Mine Expansion

Dear Hearing Examiner:

Contained herein and in the attached document are reasons why Bill Kingman's, DuPont Planning Department, and David Sherrard's, Parametrix, Inc., recommendation of approval of Glacier Northwest's Pioneer aggregate mine expansion proposal with conditions should not be approved by the DuPont Hearing Examiner.

Glacier Northwest's proposed gravel mine expansion requires, and is contingent upon, exposing and dewatering the Vashon aquifer so that mining operations can be conducted under dry mine working conditions. This would require that 6.5 million gallons per day of discharging Vashon aquifer groundwater be removed from the mine and disposed of in some fashion. Two options were proposed for disposing of this quantity of mine drainage water. One option was the creation of a 4,000 foot long interceptor channel that would convey drainage from the mine through an excavation (cut) in the Sequalitchew Creek Canyon wall for discharge into Sequalitchew Creek. This option was euphemistically called construction of North Sequalitchew Creek. The other option for disposing of mine drainage water was construction of a gravel filled interceptor ditch and buried 5,000 feet long groundwater conveyance pipeline. The down gradient 500 feet of this pipeline would be microbored (tunneled) through the existing north wall of the Sequalitchew Creek Canyon. As in the first option, 6.5 million gallons per day of mine drainage conveyed by this pipeline would be discharged into Sequalitchew Creek. The current flow in Sequalitchew Creek at the proposed point of mine water discharge is approximately 1 cubic foot per second. Mine water discharge flow into Sequalitchew Creek from either option would be from 8 to 10 cubic feet per second. This volume and velocity of discharge water entering the Creek would require construction of a rock pad and flow dissipater structure within Sequalitchew Creek proper to prevent scouring of the creek bed and adjacent Canyon walls. Dewatering the Vashon aquifer at the expanded mine site would lower the groundwater table in the vicinity of Sequalitchew Creek to the extent that groundwater discharge into the middle reach of Sequalitchew Creek would be diminished and its flow above the mine drainage discharge point reduced to half its present flow with adverse impact on stream dependent vegetation, fish and wildlife.

Excavating the Sequalitchew Canyon wall or boring through the wall to install a 500 foot pipe to facilitate the discharge of 6.5 million gallons per day of mine drainage water into Sequalitchew Creek, constructing a rock pad and flow dissipater structure in the Creek and reducing natural groundwater discharge into the middle reach of Sequalitchew Creek all constitute significant, and permanent, adverse environmental impacts in historic

Sequalitchew Creek Canyon and in the Creek itself, and therefore should not be allowed under DuPont's sensitive area ordinances.

The mitigation that Glacier Northwest proposed for the destruction of Kettle Wetlands and Seep and Riparian Forest, the adverse environmental impacts on Old Fort Lake, Pond Lake and Edmond Marsh caused by groundwater table drawdown (a result of Glacier Northwest's dewatering the Vashon aquifer), and degradation in the appearance, character and natural functioning of lower Sequalitchew Creek and its associated brackish marsh was to add features to the mine drainage interceptor channel so that it would resemble, though likely not function, as a salmon bearing stream. Additional mitigation that Glacier Northwest proposed was construction of an adjacent 5.5 acres of scrub-shrub wetlands, which are of little use to salmon. The only mitigation proposed by Glacier Northwest for construction of the gravel filled interceptor ditch and 5,000 foot long pipeline option was a dubious claim that it would enhanced salmon habitat in Sequalitchew Creek below the point of its mine drainage water discharge into the Creek.

Kingman and Sherrard rejected approval of Glacier Northwest's North Sequalitchew Creek option on the basis that removal of a section of the north wall of the Sequalitchew Creek Canyon would violate the provisions of a settlement of a law suit that involved a number of interested parties. That settlement stipulated that the historic condition of the Sequalitchew Creek Canyon (and its sensitive areas) would not be impacted by any subsequent gravel mining operations.

In a curious, and fortuitous for Glacier Northwest, turn of events Kingman and Sherrard recommended approval of the so called North Sequalitchew Creek mine dewatering and drainage option, provided that this option incorporate a 500 foot pipe bored through the north bank of the Canyon wall in lieu of its being excavated. The result of this recommended conditioned approval, if permitted, would allow construction of a 3,500 foot long groundwater interception channel in the mine pit with its down stream discharge being conveyed to Sequalitchew Creek through a 500 foot pipe that has been microbored through the north wall of Sequalitchew Creek Canyon. The end of the pipe with its 8 to 10 cubic feet per second of mine drainage flow, the rock pad and flow dissipater structure would all be evident in the Sequalitchew Creek Canyon and thus likely be in violation of the no gravel mine impact provision of the existing Sequalitchew Creek Canyon settlement. In a twist of irony, this no mining activity impact allowed in Sequalitchew Canyon provision of the settlement was the basis for Kingman's and Sherrard's prohibiting excavating a cut through the Canyon wall.

Approving Glacier Northwest's proposal as conditioned to dewatering the Vashon aquifer in order to increase its take of gravel will result in lowering the groundwater table throughout the American Lake/Sequalitchew Creek watershed with widespread adverse environmental impacts and will preclude restoring its natural functioning as noted in the attachment. Glacier Northwest should not be permitted to expand their gravel mining operations as currently proposed and conditioned by Kingman and Sharrard.

# DUPONT'S APPROVAL OF GLACIER NORTHWEST'S MINE EXPANSION

## Preface

This paper is in response to Bill Kingman's, DuPont Planning Department and David Sherrard's, Parametrix, Inc, January 16, 2009 recommendation of approval for Glacier Northwest, Pioneer Aggregate Mine Expansion project, subject to DuPont's conditions. It first describes the natural (historic) condition of the American Lake-Sequalitchew Creek watershed. It then identifies the human impacts that have resulted in its degradation. This is followed by a discussion of the irreversible environmental damage that the proposed mine expansion project would have on this watershed. And it concludes with a discussion of how the American Lake-Sequalitchew Lake ecosystem could be restored.

Kingman and Sherrard advance the notion that the construction of an artificial North Fork of Sequalitchew Creek and adjacent 5.5 acres of scrub-shrub wetlands, plus the removal of invasive vegetation and planting of native vegetation in Edmond Marsh, constitute adequate mitigation for dewatering the Vashon aquifer that sustains, and maintains, the health of the upland springs, wetlands, streams and lakes of the American Lake-Sequalitchew Creek watershed. This paper presents a rationale as to why Glacier Northwest should be denied a permit to dewater the aquifer that sustains this fragile ecosystem. It makes the claim that no amount of mitigation by Glacier Northwest, should they be permitted to dewater the Vashon aquifer, will protect or preserve what little of the remaining natural condition and functioning of this watershed still exists. This paper also makes the claim that dewatering the Vashon aquifer will preclude successful restoration of the natural condition and functioning of the American Lake-Sequalitchew Creek watershed.

## The Natural Condition of the American Lake/Sequalitchew Creek Watershed

Sequalitchew Creek is located within the Chambers-Clover Washington State Water Resources Area 12 (WRIA 12). WRIA 12 is comprised of a number of sub-basin watersheds. The best known of these is the Chambers-Clover Creek Basin which is comprised of several sub-basins. Not as well known is the American Lake sub-basin. Just as Chambers Creek is the surface water drainage stream to Puget Sound for Clover Creek, Sequalitchew Creek is the surface water drainage stream to Puget Sound for the American Lake sub-basin. [See the Chambers-Clover Technical Assessment Final Report, April 10, 2003, Figure 1.1 Base Map]

Contrary to Glacier Northwest's assertion that the headwaters of Sequalitchew Creek is Edmonds Marsh, the headwaters of Sequalitchew Creek is Murray Creek (formerly called Upper Sequalitchew Creek) which flows into American Lake, the largest natural lake in Pierce County. American Lake has a surface water level significantly higher (by 20 feet) than that of Sequalitchew Lake. Because of this difference in lake levels, their close proximity and intervening porous gravel soil there is considerable subsurface (groundwater) flow from American Lake to Sequalitchew Springs and Sequalitchew Lake.

Occasionally, as a result of high groundwater levels, there is surface water flow from American Lake to Sequalitchew Lake. Surface water outflow from Sequalitchew Lake, supplemented by localized groundwater discharge from the Vashon aquifer, provided the water that sustained an extensive complex of Class I wetlands and Sequalitchew Creek.

The source of water that sustained and nourished the American Lake-Sequalitchew Creek watershed (ecosystem) was precipitation in the form of rainfall. The shallow gradient of this watershed and its permeable soils allowed precipitation to infiltrate into the ground where it fell rather than run off into its streams, wetlands and lakes. Several natural water conditioning processes were important to the proper functioning of this watershed. Precipitation falling on vegetated soil was cleansed of airborne pollutants (oxides of nitrogen, phosphorus and sulfur) as a result of their being assimilated by plants and adsorbed to fine grained topsoil particles. These airborne pollutants were primarily from volcanic eruptions, naturally occurring forest fires and the burning of grasslands by native Americans. Infiltrating rainwater percolating through topsoil beneath the vegetative cover picked up respired carbon dioxide from soil bacteria. This functioned to impart a degree of acidity to infiltrating rain water. Mildly acidic water percolating through underlying soil dissolved calcium from gravel deposits to form water soluble calcium bicarbonate. Calcium ions in water moderate fish gill function and must be present in appropriate concentration to assure proper functioning of gill tissue. Bicarbonate ions functioned as important buffers. Buffers prevent water from becoming either too acidic or too alkaline to support salmon. Chemically conditioned infiltrating water became the substance that comprised the Vashon aquifer. The gravel deposits of the Vashon aquifer functioned as a sponge that both stored groundwater and slowly released (discharged) it to springs, streams, wetlands and lakes. Vashon aquifer groundwater discharge was the natural and historic source of water for the springs, streams, wetlands and lakes in the American Lake-Sequalitchew Creek watershed.

Groundwater is insulated from the effects of fluctuations in surface temperature. Its temperature stabilizes and remains at approximately 50 degrees F throughout the entire season. Groundwater, under the influence of gravity, flows slowly through gravel soils from areas of higher elevation to areas of lower elevation. It ultimately surfaces (discharges) with its physical (low temperature) and chemical (calcium and bicarbonate) properties intact to become the water that flows from a spring or becomes the water in a salmon friendly stream, wetland, or lake, or discharges subsurface into Puget Sound. Salmon evolved, and thrived, in clean, cool, well oxygenated, calcium rich and buffered fresh water habitats. Eventually salmon commenced migrating to saltwater where food was more plentiful than in their freshwater habitat. Making a transition from a fresh water environment to salt water environment and the reverse requires major physiological changes in the functioning of fish gills. This transition takes time and is facilitated by salmon spending time in the fresh-salt (brackish) water estuaries which were located at the mouth of all salmon bearing streams.

There are natural seasonal and long term fluctuations in the amount of precipitation falling on the American Lake/Sequalitchew Creek watershed. These fluctuations affect groundwater levels. During the wet season, or prolonged periods of precipitation,

groundwater levels are high (as a result of recharge) as is groundwater discharge to springs, stream, wetlands and lakes. During the dry season, or periods of drought, groundwater levels are low which diminishes the volume of groundwater discharged to springs, streams, wetlands and lakes. Under extremely dry conditions (or as a result of humans limiting the amount of infiltration of precipitation to groundwater or withdrawal of groundwater for consumption) streams, wetlands and lakes can loose their connectivity with groundwater. When this occurs water from surface water bodies will infiltration (leak) into adjacent and underlying unsaturated soils with the result that spring and stream flows diminish or disappear all together and wetland and lake levels drop, or result in their drying up completely, with adverse effects on native species of vegetation, fish, and wildlife. It is this condition, whether naturally occurring or brought about by human impact, that favors the displacement of native vegetation and establishment of invasive species.

Under natural (historic) conditions wet season increase in groundwater discharge to streams, wetlands and lakes had several desirable effects. It increased stream flows sufficiently to provide salmon access to suitable spawning habitat. Increased groundwater discharge into streams back flushed (dislodged) the fine grained sediments that had accumulated in the stream bed during dry season low flow periods. Re-suspended sediment particles were flushed out of the system by stream flows enhanced by contributions from groundwater flooded upstream wetlands and lakes. Stream beds cleansed of silt by this natural process provided salmon optimum stream bed conditions for spawning. During the dry season cool, dissolved oxygen and calcium enriched, and buffered groundwater discharging into streams, wetlands and lakes provided optimal environmental conditions for salmon egg survival and the rearing of young salmon.

Prior to 1850 the natural conditions and watershed functions described above prevailed throughout the American Lake/Sequalitchew Creek watershed. Sequalitchew Creek was a perennial stream with a discharge of from 10 to 20 cfs that flowed into a fresh-salt water estuary. As a result the American Lake/Sequalitchew Creek watershed was home for coho, sockeye and chum salmon, sea run cutthroat trout and steelhead (rainbow trout) and supported a viable Indian fishery. All this began to changed when white European settlers arrived in this area and began to "develop" the American Lake/Sequalitchew Creek watershed

**Degradation of the American Lake/Sequalitchew Creek Watershed**

In the middle 1800s and early 1900s the American Lake-Sequalitchew Creek watershed was adversely affected by timber harvesting in the Sequalitchew Canyon. This led to instability of its canyon walls and increased silting of the lower reach of Sequalitchew Creek. This condition was exacerbated when the fresh-salt water estuary at the mouth of Sequalitchew Creek was transected by a railroad bed. A five by five foot culvert was constructed to allow water exchange between Sequalitchew Creek and Puget Sound. The constriction in water flow caused by the undersized culvert allowed silt to accumulate and eventually fill in the upper portion of the fresh-salt water estuary thus destroying its function as a salt-to-fresh/fresh-to-salt water transition zone for salmon.

In 1916 when Fort Lewis was being developed American Lake's level was 239 feet above msl. [TNT article 10/8/51] American Lake is a major source of recharge to the Vashon aquifer during the dry season. It also provides a prolific subsurface flow to down gradient Sequalitchew Springs. As part of the development of Fort Lewis the Army Corps of Engineers tapped Sequalitchew Springs as the domestic water source for personnel serving on the Army base. After domestic use most of the water withdrawn from Sequalitchew Springs was returned (as recharge) to the Vashon aquifer by way of infiltration from septic systems. Thus there was little adverse effect on groundwater levels and impact on the watershed as a result of the Army's consumptive use of Sequalitchew Springs water. Later, however, water withdrawn from Sequalitchew Springs would, after its use, enter sewer lines and be conveyed to the Army's Solo Point sewage treatment plant for discharge into Puget Sound. Thus Vashon aquifer recharge in the Sequalitchew Creek basin was diminished as was groundwater table level.

American Lake's shoreline, not owned by Fort Lewis, Camp Murray and the Veterans Hospital, was extensively developed during the period from 1920 through the 1940's. This development took place during a period of below average precipitation in the American Lake watershed when the lake had dropped and remained below 235 feet above msl. Whereas old time residents who were familiar with the natural seasonal and decadal rise and fall of American Lake level built their homes upland from the lake, newcomers to American Lake built their homes close to the lake shore.

In 1951, as a result of several years of increasing precipitation, American Lake level rose to 237 feet above msl. The result was extensive groundwater flooding of shoreline homes and septic systems around the lake that had been built during the period of low water. Lakeshore residents complained and asked the U.S. Army Corps of Engineers to construct a groundwater flood control structure at their end of the lake that would prevent groundwater flooding damage to lake side homes and septic systems. The Army's position at that time was that it had no responsibility to mitigate the impact of high lake water level. Their argument was that the lake level in 1951was two feet below the 239 foot above msl level that existed when the Army first began developing Fort Lewis in 1916 and that the lake level rise to 237 feet above msl was a natural condition.

Extensive groundwater flooding in the American Lake-Sequalitchew Creek watershed occurred again in 1956. [TNT article 1/10/56] This time the groundwater flooding adversely affected properties owned by the Army, notably their Sequalitchew Springs domestic water works and some of the Army facilities that had been constructed near wetlands during the 1920 to 1950 period of low groundwater levels. 1956's groundwater flooding of wetlands located near these facilities was exacerbated by the Army's practice of conveying surface water runoff from impervious surfaces to these wetlands. The impact of draining surface water runoff to wetlands and superimposing it on ground water flooded wetlands was a sobering new experience for the people at Fort Lewis.

In response to 1956's ground and surface water flooding event the U.S. Army constructed a groundwater flood control weir at the south end of American Lake. It was designed to

prevent American Lake level from exceeding 233 feet above msl. It also constructed a means of controlling Sequalitchew Lake's level so that it could no longer rise to levels that would endanger its Sequalitchew Springs domestic water supply. Provisions were also made to control the water level in wetlands located in close proximity of Army facilities constructed during the period of low groundwater levels. The flood control structure that was built to deal with these two issues was comprised of a weir complex at the south end of Sequalitchew Lake and a flood water diversion canal. The purpose of these two structures was to convey flood water affecting Sequalitchew Lake and related marshes to Puget Sound, yet still provide headwater flow for Sequalitchew Creek. Under natural conditions the surface flood water routed to Puget Sound via the diversion canal would have infiltrated into permeable soils to recharge the Vashon aquifer and thus sustain the groundwater level (water table) necessary to maintain the proper functioning of Edmond Marsh and Sequalitchew Creek. Unfortunately the diversion canal as now operated has functioned to "dewater" (by lowering the water table) the upper reach of Sequalitchew Creek and reduced water levels in Edmond Marsh and related wetlands.

Lowering American Lake's water level from 239 to 233 feet above msl, withdrawing groundwater from Sequalitchew Springs to meet the U. S. Army's need for a domestic water supply, diverted Sequalitchew Springs water, after use, to the Solo Point sewage treatment plant for discharge to Puget Sound, increasing impervious surfaces thus reducing groundwater recharge, diverting most of Sequalitchew Lake's and related wetlands' groundwater contribution and surface water runoff down the diversion canal to Puget Sound all conspired to lower mean groundwater levels throughout the American Lake/Sequalitchew Creek watershed by approximately six feet over a span of 100 years. The cumulative effect of these actions reduced historic Sequalitchew Creek perennial flow to Puget Sound from 10 to 20 cfs to 1 to 2 cfs.

The practice of using natural and historic wetlands as surface water runoff treatment, detention and infiltration ponds has contributed significantly to the degradation of the American Lake-Sequalitchew Creek watershed. When surface water runoff is introduced into groundwater fed streams, wetlands and lakes it changes the physical and chemical properties of their water and alters their biological response in ways that degrade their natural functioning and suitability as fish and wildlife habitat. What occurs is a dramatic increase in the range of water levels fluctuations (e.g., streams and wetlands experience alternating periods of flooding and drying), anoxic and toxic bottom sediments build up as a result of accumulations of particulate matter conveyed by surface water runoff, water stagnates leading to dry season high water temperatures and low dissolved oxygen, fish and amphibian kills occur, native plants, fish and wildlife are displaced by invasive species, toxic algae blooms occur in ponds and lakes and estuaries are lost due to sediment build up and pollution. These water quality problems are now prevalent throughout much of the Chambers-Clover Creek watershed and are of particular concern when considering the likely fate of the American Lake-Sequalitchew Creek ecosystem should Glacier Northwest be permitted to dewater the Vashon aquifer.

In summary, man's past activities in the American Lake/Sequalitchew Lake watershed has resulted in lower groundwater levels. As a result groundwater connectivity with

springs, streams, wetlands and lakes has been either compromised or lost. Furthermore human activity in the watershed has resulted in the pollution of streams, wetlands, lakes, and estuaries, and the groundwater source upon which these surface water bodies depend for their natural functioning.

**Glacier Northwest's Motivation for Dewatering the Aquifer in the Gravel Mine**

The motivation on the part of Glacier Northwest for dewatering the aquifer is clear. It is to increase its take of gravel from the mine and to do so under relatively dry working conditions. In order to assure citizens that dewatering the aquifer would not degrade historic Sequalitchew Creek, and gain the support of the Nisqually Tribe, Glacier Northwest engaged consultants to develop and document a rationale that would support the notion that Glacier Northwest's dewatering of the aquifer would have a favorable environmental impact on lower Sequalitchew Creek that would far outweighed any adverse environmental impact on upland Sequalitchew Creek, Edmond Marsh, Sequalitchew Lake and Sequalitchew Springs. The promised environmental mitigation for Glacier Northwest's further degradation of historic Sequalitchew Creek (by dewatering the Vashon aquifer) is construction of a groundwater interception and diversion channel (seductively named North Fork Sequalitchew Creek) that would flow to lower Sequalitchew Creek. Their claim is that this constructed stream, with associated scrub-shrub wetlands, would enhance lower Sequalitchew Creek's flow and provide suitable habitat for salmon and sea run trout species. The EIS done by Glacier Northwest and its consultants was drafted with this objective in mind and should be viewed in this context. Unfortunately Kingman's and Sherrard's recommendation that Glacier Northwest's proposal be approved, with minor modification (mitigation), is based upon inadequate, incomplete and biased information which is contained in the EIS provide by Glacier Northwest about the likely environmental impact of its proposal on the functioning of the American Lake-Sequalitchew Creek watershed.

**Glacier Northwest's Proposed Gravel Mine Expansion**

Glacier Northwest's proposed 177-acre gravel mine expansion will involve the removal of 184 acres of forest and topsoil. It will create a 550-acre hole in the underlying gravel as 40 million tons of gravel is extracted over the next 14 years. The pit will be 80 feet deep and will require dewatering the Vashon aquifer to avail itself of this much gravel. The flow from this exposed aquifer (estimated at approximately 6.5 million gallons per day) will be directed down a constructed groundwater diversion channel (North Fork of Sequalitchew Creek) to the lower reach of Sequalitchew Creek with a flow eight times that of present Sequalitchew Creek. Dewatering the aquifer will lower the groundwater level in the vicinity of the mine by as much as 30 feet and is anticipated to lower groundwater levels beneath upper Sequalitchew Creek and water levels at Edmond Marsh and Sequalitchew Springs by lesser amounts.

Glacier claims that this dewatering of the exposed aquifer will reduce groundwater levels by 3 inches at Sequalitchew Springs which supply Fort Lewis with its drinking water. It would cut in half the flows in the groundwater fed middle reach of Sequalitchew Creek.

The upper reach already frequently runs dry during the summer months as a result of low groundwater level, i.e., water table. DuPont is concerned about this project's impact on culturally and environmentally important Edmond Marsh. Glacier claims that lowering the water table by 18 inches will not adversely impact Edmonds Marsh. Glacier also claims that DuPont's drinking water wells should not be adversely affected.

**Commentary on Glacier Northwest's Proposal and City of DuPont's Approval**

On January 16, 2009 DuPont's Community Development Department recommended approval of [Glacier Northwest's] proposed aggregate mine expansion with conditions. The approval would allow/require:

1. Expansion of aggregate removal throughout the 177 acres proposed.

2. Groundwater aquifer dewatering to lower the water table for access to additional aggregate.

3. Mitigation for potential groundwater aquifer drawdown impacts on Edmonds Marsh.

4. Removal of the "Kettle Wetland"

5. Displacement of wetland functions at the Seep and Riparian wetlands.

6. Mitigation for potential impacts on public water supplies provided by groundwater

The approval would not allow the evacuation of the north side of the existing Sequalitchew Creek ravine but would, instead, require installation of a micro-bored pipeline approximately 500 feet long.

The rationale offered to justify approval of Glacier Northwest's proposed actions, as modified by DuPont's conditions, and this author's argument against approving Glacier Northwest's proposed actions, as modified by DuPont's conditions, follows.

<u>Removal of 184 Acres of Forest and Top Soil and 40 Million Tons of Underlying Gravel</u>

The removal of 184 acres of forests and topsoil would destroy wildlife habitat and the cleansing function (assimilation of nitrates, phosphates and pollutants) performed by vegetative cover. It would destroy the cleansing function (adsorption of phosphates and toxic metals) performed by top soil fine grained particles and the water conditioning function of respiring soil bacteria (carbon dioxide acidification). It would remove 40 million tons of underlying gravel that is the source of calcium and bicarbonate that are essential requirements for salmon, and become available to them when groundwater is discharged into streams, wetlands and lakes. It would eliminate a large reservoir of groundwater that would have otherwise been retained (stored and time released) in the gravel that is to be removed. And, it would breach the gravel "dam" that holds back and maintains the current (but degraded) groundwater level (water table) that sustains "Kettle

Wetland", the Seep and Riparian Forest, Sequalitchew Springs, Sequalitchew Lake, Old Fort Lake, Pond Lake, Edmond Marsh (and related wetlands) and Sequalitchew Creek.

Groundwater Aquifer Dewatering to Lower the Water Table for Access to Additional Aggregate

The allowed use was to mine gravel, not destroy sensitive areas that are dependent upon their connectivity with groundwater for their continued existence and ongoing sustenance. The destruction of "Kettle Wetland" and the Seep and Riparian Forest certainly modifies sensitive areas within the mine proper. Dewatering the aquifer also modifies sensitive areas far outside the confines of the mine (as noted above), all of which would otherwise be prohibited or require effective mitigation under sensitive area ordinances. The sole mitigation proposed by Glacier Northwest for dewatering the aquifer is construction of an artificial North Fork of Sequalitchew Creek and construction of associated wetlands. The constructed stream bed would rest on till which would reduce water loss due to infiltration, however it would effectively negate the stream bed as suitable salmon spawning habitat. The constructed wetlands proposed are of the scrub-shrub type that do not provide off channel habitat for coho salmon rearing and therefore don't make up for the loss of Edmond Marsh off channel habitat that will be caused by dewatering the Vashon aquifer. North Fork water and its impact on Sequalitchew Canyon walls will add considerably to the silt load that has already filled in and destroyed the estuary at the mouth of Sequalitchew Creek upstream of the railroad embankment. As mentioned above, fresh-salt water estuaries are essential in facilitating a salmon's salt-to-fresh or fresh-to-salt water transition. Apparently DuPont feels that construction of a so called North Fork of Sequalitchew Creek (in reality a Vashon aquifer dewatering collection and drainage channel) is adequate mitigation, with conditions, for Glacier Northwest's proposed expansion of its gravel mine. DuPont conditioned this proposed mitigation by requiring that the north wall of the Sequalitchew Canyon not be removed but instead be breached by a 500 foot long pipe. This pipeline would render the upstream (daylighted) portion of the constructed groundwater drainage channel (North Fork) all but useless as salmon habitat. It is interesting to note that Herrera's 2005 Technical Report included, as an alternative to construction of a North Fork of Sequalitchew Creek, a gravel filled interceptor ditch and a buried conveyance pipeline 5,000 feet long, with its down gradient 500 feet micro- tunneled through the berm (Canyon wall). Groundwater seepage from the mine would discharge into Sequalitchew Creek at the point envisioned for North Fork discharge. DuPont's condition appears to attempt to combine features from both the North Fork Sequalitchew Creek and gravel filled interceptor ditch mitigation proposal neither of which provide suitable habitat for salmon.

Mitigation for Potential Aquifer Drawdown Impacts on Edmond Marsh

Glacier Northwest's proposal claims that the projected groundwater table draw down as a result of its dewatering the Vashon aquifer will be 18 inches at the west end of Edmonds Marsh. It also claims that Edmond Marsh should not be impacted by this water table drawdown because the Marsh is supplied by surface water, not groundwater.

The natural condition of Edmond Marsh was that of a groundwater supplied and stream connected wetland that provided optimum off channel habitat for rearing young salmon and a necessary dry season refuge (with its cool, well oxygenated, calcium and bicarbonate enriched water) for young salmon, trout and other forms of resident aquatic life.

Glacier Northwest's position is that even if there was an impact it would be inconsequential when compared to the water level fluctuations caused by variation in the amount of surface water input that Edmond Marsh receives.

The surface water source to which Glacier Northwest refers is surface water runoff from impervious surfaces, which is an unnatural and highly fluctuating source. Glacier Northwest anticipates that the impact of groundwater drawdown will increase the period of low or no water in the Marsh during the dry season by 2 months (from 6 to 8 months). The groundwater model that was used to arrive at this drawdown figure is highly suspect in that it implies that the area of environmental impact that dewatering the Vashon aquifer is likely to have will be primarily confined to the west end of Edmond Marsh and the middle reach of Sequalitchew Creek. A similar groundwater model was used by Robinson & Noble, Inc. consultants for the Lakewood Water District to determine the drawdown that would occur as a result of withdrawing an additional 5.0 million gallons per day of groundwater from their existing wells [vs. Glacier Northwest's dewatering the Vashon aquifer at the rate of 6.5 million gallons per day]. The impact of this additional withdrawal extended from Lakewood all the way out to Fredrickson a distance of some 12 miles and the groundwater level drawdown was in multiple feet not inches. Edmond Marsh is located 1 mile from the mine dewatering site.

Glacier Northwest offered no mitigation in its proposal for the adverse environmental impacts that lowering the groundwater water table would have on other sensitive areas in the American Lake-Sequalitchew Creek watershed.

DuPont has conditioned its approval of Glacier Northwest's proposal by requiring that Glacier Northwest remove invasive vegetation and plant native vegetation in a small portion of Edmond Marsh. This mitigation will not begin to address the problems that will be created in Edmond Marsh by lowering groundwater levels by 18 inches. The effect of dewatering the Vashon aquifer will be to destroy much of Edmonds Marsh as suitable habitat for native plants, as well as for salmon rearing and wildlife. As is already evident by the infestation by reed canary grass in the shallow portions of Edmond Marsh a further lowering of the groundwater table beneath Edmond Marsh together with the flashy nature of surface water runoff will significantly increase the area of the Marsh inhabited by invasive species. Any native vegetation planted will not survive under the conditions created by 18 inches of groundwater drawdown and periodic influxes of surface water runoff.

Effective restoration of Edmond Marsh as a naturally functioning wetland will require management of groundwater levels so as to restore its connectivity with groundwater and the discontinuance of the practice of conveying untreated surface water runoff from

impervious surfaces into the Marsh. The alternating wetting and drying of wetlands not only destroys their function as fish and wildlife habitat, but also as nutrient, toxic metal and organic compound sinks. When subjected to alternate periods of wetting and drying wetlands become sources of nutrients (nitrates and phosphates) and toxic metal pollution that adversely affect surface and ground water quality.

Removal of the "Kettle Wetland"

It is interesting to reflect of the following words of Glacier Northwest: *The construction of North Sequalitchew Creek and the benefits resulting from the additional flow in lower Sequalitchew Creek cannot be accomplished with out removing* [Kettle Wetland and Seep Wetland]. *Furthermore, mining in the expansion area would dewater these wetlands regardless of whether the wetland and their buffers were mined.* Glacier Northwest claims, and apparently DuPont concurs that construction of a North Fork of Sequalitchew Creek and 5.5 acres of scrub-shrub wetland more than offsets the destruction of this natural and sensitive area. The track record of constructed wetland actually functioning as wetlands is very poor.

Displacement of Wetland Functions at the Seep and Riparian Wetlands

The proposal indicates that the natural functions at the Seep and Riparian Wetlands sensitive areas would be destroyed. The proposed mitigation for this destruction would consist of construction of the aforementioned 5.5 acres of scrub and shrub wetlands.

Mitigation in Case of Impacts on Public Water Supplies Provided by Groundwater

Glacier Northwest proposed no mitigation for the impact that dewatering the Vashon aquifer will likely have on public water supplies. DuPont states that should the groundwater drawdown resulting from Glacier Northwest's dewatering of the Vashon aquifer adversely impact Fort Lewis' Sequalitchew Springs domestic water source that the mitigation required would be for Glacier Northwest to replace Fort Lewis' domestic water source by constructing a well (or wells). This well (or wells) would withdraw water from an aquifer lying beneath the Vashon aquifer, i.e., from the sea level aquifer. This is impractical in several respects. Sea level aquifer water has a higher dissolved mineral content than water drawn from the Vashon aquifer and, in certain areas, has high concentrations of iron, manganese and arsenic. Operating and maintaining a deep well, acquiring and operating facilities to treat water containing high concentrations of iron and manganese, and possibly arsenic, would incur costs that are much higher than the costs of operating the existing Fort Lewis water works. And then there is the issue of obtaining a new water right for withdrawals from the sea level aquifer. Currently WRIA 12 is a closed basin in regard to the issuance of new water rights.

An unintended impact that could adversely affect DuPont's existing domestic water supply provided by groundwater is an increase in nitrate and toxic metal concentrations in groundwater. Alternating periods of wetting and drying wetland sediments result in the mineralization of organic matter. Nitrates and soluble forms of toxic metals are

produced as a result of mineralization of wetland sediments. Whereas DuPont's wells withdraw groundwater from an aquifer (the sea level aquifer) beneath the Vashon aquifer the till layer that separates the Vashon aquifer from the sea level aquifer is discontinuous, i.e., there are windows that permit Vashon aquifer water to flow down into the sea level aquifer carrying with it any pollutants contained in Vashon aquifer water. Nitrates and soluble forms of toxic metals are a health hazard to humans and therefore could threaten the quality of DuPont's groundwater supply.

Claim that Construction of an Enhanced Aquifer Dewatering Drainage Channel is Adequate Mitigation for the Watershed Degradation that Glacier Northwest's Aggregate Mine Expansion will Cause

Glacier Northwest's claim is that: *The new North Sequalitchew Creek will provide additional fish habitat and improve the water supply to the existing Sequalitchew Creek that will enhance spawning and rearing conditions for fish in the portions of the existing creek downstream of the confluence with the new stream.* The natural and historic condition of Sequalitchew Creek was that of a productive salmon bearing groundwater fed stream that allowed salmon to migration through fresh-salt water mixing zones (estuaries) from Puget Sound to Sequalitchew Lake, provided clean gravel spawning beds, offered off channel wetland habitat for the successful rearing of young salmon who require cool, dissolved oxygen rich, calcium and bicarbonate enhanced water during the dry season and adequate aquatic plants among which they can hide from their predators. Glacier Northwest's propose gravel mine expansion that features dewatering the Vashon aquifer will, if permitted, result in further degradation or destruction of the American Lake-Sequalitchew Creek watershed as desirable habitat for native plants, fish, wildlife and people.

Glacier Northwest's proposed aggregate expansion should be denied by DuPont and/or the Hearing Examiner on the basis that its execution, as proposed, will cause unintended, permanent and irreversible damage to environmentally sensitive areas in DuPont and throughout the American Lake-Sequalitchew Creek ecosystem.

The following excerpt from Puget Sound Partnership's 2020 Action Agenda seems a fitting way to conclude this section: *"The alteration and loss of habit and the ongoing input of pollution are the top two immediate and pervasive threats facing Puget Sound."*

**Restoration of Historic Sequalitchew Creek**

One of the six announced goals of the Puget Sound Partnership is: *"An ecosystem that is supported by ground water levels as well as river and stream flow levels sufficient to sustain people, fish, wildlife, and the natural functions of the environment."*

In spite of the extent and magnitude of degradation that has occurred in the American Lake-Sequalitchew watershed during the past 150 years much of this degradation can be mitigated, i.e., its ecosystem can largely be restored. American Lake level can be raised from 233 feet to 235 feet above msl by simply raising the height of the south end weir by

two feet. The diversionary canal at the south west end of Sequalitchew should be used only to mitigate the occasional adverse impact of area wide surface and groundwater flooding. Discharge from Sequalitchew Lake and related wetlands should be allowed to either flow down Sequalitchew Creek or infiltrate to recharge groundwater rather than be lost to the watershed by its conveyance via the diversion canal to Puget Sound. Sequalitchew Spring domestic water supply can be returned to groundwater after use and treatment by allowing it to infiltrating and recharge the Vashon groundwater aquifer up gradient of I-5 rather than piping it to the Solo Point sewage treatment facility and subsequently discharging it into Puget Sound. This mitigation would provide the additional benefit of stopping the discharge of millions of gallons per year of nutrient rich effluent into already degraded South Puget Sound. The practice of using natural wetlands as surface water runoff detention, treatment, and infiltration ponds should be discontinued. These functions should be separated with detention and treatment being carried out in constructed and maintained detention and treatment ponds that function to remove sediments, nutrients and pollutants from surface water runoff. The cleansed surface water runoff could then be released to existing natural wetlands to maintain their natural hydrologic functioning. The former, but now sediment filled, brackish marsh at the mouth of Sequalitchew Creek could be restored as a salt-to-fresh and fresh-to-salt water transition zone for salmon by the removing the accumulated sediments that now render it ineffective for this purpose.

By restoring and maintaining near historic groundwater levels increases in steam flows and wetland and lake levels would follow. By protecting, maintaining and restoring native vegetation and top soil their water cleansing and conditioning functions would be restored. By preventing aquifer dewatering and gravel removal from sensitive areas their storage capacity and slow time release of cool clear, clean water into streams, wetlands and lakes would be sustained. If these things were done PSP's goal to *"... sustain people, fish, wildlife, and the natural functions of the environment."* would be realized in the American Lake-Sequalitchew Creek watershed.

**The Benefits of Restoring the Historic Sequalitchew Creek Corridor**

Restoration of the historic Sequalitchew Lake to Puget Sound salmon and wildlife corridor would provide the following benefits.

- Salmon access to their historic and natural spawning grounds and over-the-dry season salmon young (smolts) rearing habitats (i.e., groundwater fed marshes).

- In addition to restoration of chum and coho salmon runs there exists the possibility of restoration of sockeye salmon populations once access to groundwater fed Sequalitchew Lake is re-established.

- A restored and functioning salmon bearing stream running through the heart of the City of DuPont would enhance the City's attractiveness for residents and a major draw for tourists.

- The natural hydrology of the American Lake sub-watershed would be restored which would assure healthy and natural functioning of the many springs, streams, wetlands and lakes that comprise this watershed.

- Groundwater quantity and quality would improve as a result of restoration of the natural functioning of the extensive wetlands and the ponds and lakes than are features of this sub-watershed. Wetlands function to remove pollutants from surface water prior to its infiltrating to recharge underlying aquifers. They provide over-the-dry season refuge for young salmon. And they store and release surface water to recharge the aquifers (as do the ponds and lakes) upon which domestic water supplies depend during the dry season.

- There is far greater certainty that salmon would return in sustainable numbers, and much sooner, to a restored historic Sequalitchew Creek than they would to a degraded lower Sequalitchew Creek and brackish marsh and a constructed, and highly questionable, North Fork Sequalitchew Creek that can only be accessed by salmon passing through a 500 foot long pipe.

None of these benefits can be realized if Glacier Northwest is allowed to dewater the Vashon aquifer in order to increase its take from their DuPont gravel mine. There is simply no effective mitigation for the extensive removal of natural vegetation, top soil, and water bearing gravel soil and loss of hundreds of acres of upland Class 1 wetlands that Glacier Northwest's mine expansion and dewatering of the Vashon aquifer will cause.

**Conclusion**

The natural condition of the American Lake-Sequalitchew Creek watershed is best describe as its being a precipitation, infiltration, water conditioning, groundwater storage and discharge to surface water bodies hydrologic system. Surface water bodies reflected discharging groundwater physical and chemical attributes. Water in streams and lakes was cold, clear, devoid of excessive nutrients, toxic materials and sediments. Fluctuations in seasonal stream flows and wetland and lake levels were dampened (muted) as a result of the storage capacity and delayed response of groundwater discharge to variations in precipitation. Native plants, salmon and trout, amphibians, birds and wildlife evolved, were attuned to, thrived and their populations sustain in this environment.

In the past 150 years human activities have altered this natural condition. Groundwater recharge has been diminished as a result of impervious surfaces and the practice of draining surface, waste stream and flood water to Puget Sound. Groundwater has been polluted as a result of infiltrating untreated waste water (septic effluent) and runoff water into gravel soils. Groundwater withdrawals have increased to provide water for domestic and industrial consumption. As a result the natural functioning of the American Lake-Sequalitchew Creek has been degraded. Glacier Northwest proposes to further degrade this watershed. It should not be permitted to do so.

Renee,

You apparently wanted me to provide compelling legal arguments that would convince the Hearing Examiner to reject CalPortland's argument in support of dewatering the Vashon aquifer, find in favor of the City of DuPont's presumed desire to prevent the dewatering of the Vashon aquifer, and negotiate a more equitable and sustainable win-win arrangement in regard to the future beneficial use of the DuPont mined out gravel pit.

I previously submitted the attachment in this regard. I again attached it to this email for your review and submission to the City of DuPont's Hearing Examiner.

Best regards,

Don

## AN EXAMINATION AND EVALUATION OF ALTERNATIVE 2.1.6

### Preface

This paper examines and fatal flaw evaluates Alternative 2.1.6 Infiltrate Stormwater and Groundwater Discharges to Recharge Puget Sound Springs. It does so by reciting passages from the March 25, 2010 Draft Feasibility Study (in italics), providing evaluation commentary (in this print format) and offers a conclusion regarding its fatal flaw status.

### Relevant Passages and Commentary

*"The purpose of the Feasibility Study is to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."*

*"…surface water features within the Sequalitchew Creek basin are hydraulically connected and interact with the groundwater system."*

*"It is these mingled Vashon Aquifer and sea level aquifer waters that form the Puget Sound shoreline springs, referred to as the Large and Small Springs north of the mouth of Sequalitchew Creek."*

*"Groundwater discharges as springs and seeps in the lower Sequalitchew Creek…and provides the majority of creek baseflow which varies between approximately 0.5 cubic feet per second (cfs)(summer) and 1.5 cfs (winter).* Dewatering the Vashon aquifer and excavating gravel in the South Expansion Area at or below the elevation of the adjacent Sequalitchew Creek bed will cause diminishment or cessation of base flow in Sequalitchew Creek. This is clearly a violation of the no impact provision of the 1994 Agreement.

*"The post-mining groundwater discharge is predicted to average about 7 cfs and range seasonally from 6 to 9 cfs."*

*"A 1.78-acre kettle wetland is located in a large, closed depression that lies near the center of the existing mine site. The kettle wetland vegetation communities are relatively susceptible to changes in groundwater hydrology, which directly control water levels in the wetland."* Alternative 2.1.6 would eliminate this Class 2 wetland. Such an act would be in violation of a provision (25 foot buffer) of CalPortland's current mining permit and the City of DuPont's municipal code DMC 25.105.070.1(f).

*"West Edmond Marsh is an approximate 135-acre wetland with a hydraulic regime dominated by surface water inputs to the south and east."* Alternative 2.1.6 would impact this Class 1 wetland by lowering the groundwater level 1.5 feet beneath West Edmond Marsh. The City of DuPont's municipal code DMC 25.105.070.1(f) states that alteration of Class 1 wetlands is prohibited.

*"A 0.13-acre seep wetland complex of two long, very narrow, and non-contiguous wetlands is located just above the trail along Sequalitchew Creek at about RM 0.75 to 0.85."* Alternative 2.1.6 would disconnect this wetland complex from the groundwater source that sustains it. The elimination of this seep wetland complex would be in violation of DMC 25.105.070.1(f). Since the water that flows from this wetland discharges into Sequalitchew Creek such an act would be in violation of the 1994 Agreement.

*"The underlying zoning of the mine site is a mix of residential (North Expansion Area) and manufacturing and industrial (South Expansion Area) designations, and the mine is included within a mineral resources overlay. Mining activities are considered a temporary use and are consistent with the underlying zoning. Future land use is an important consideration in any alternative proposed for this study."* RCW 78.44.031(11) states that "Although both the need for and practicability of reclamation will control the type and degree of reclamation in any specific surface mine, the basic objective shall be to reestablish on a perpetual basis the vegetative cover, soil stability, and water conditions appropriate to the approved subsequent use of the surface mine and to prevent or mitigate future environmental degradation." 6 to 9 cubic feet per second of discharging groundwater emanating from the east sloping face of the South Expansion Area and flowing out onto exposed impervious Olympia Bed soil and its commingling with stormwater runoff poses an in perpetuity problem that neither industrial tenants or the City of DuPont should have to face. Such a scenario seems in clear violation of the basic objective of mine reclamation as cited in RCW 78.44.031(11). Furthermore, to convey this quantity of groundwater and commingled stormwater runoff to the central mine area and North Expansion Area for treatment and infiltration seems incongruous with the intended residential use of these areas of the spent mine as well.

*"Mining is permitted only above the aquifer and a 25-foot separation (10-foot separation for slopes) is required between mining activities and the seasonal high groundwater level. Stormwater is managed onsite through infiltration."* [Page 25, lines 19 – 22] This is a current restriction in CalPortland's aggregate mining permit. This restriction makes good environmental sense in that: *"…surface water features within the Sequalitchew Creek basin are hydraulically connected and interact with the groundwater system."* Alternative 2.1.6 would adversely impact the surface water features of Kettle, Seep and Edmond Marsh wetlands and Sequalitchew Creek since they are all hydraulically connected and interact with the groundwater system that CalPortland proposes to dramatically alter by dewatering the Vashon aquifer that sustains these critical and sensitive surface water bodies.

*"The goal of the alternatives in this section is to avoid, minimize, and/or mitigate any change to the aquifer levels in the project area. These alternatives would also avoid and minimize any change to the flow of Sequalitchew Creek from current levels."* [Page 28, lines 25 – 27] Note the subtle shift in the above language from that stated as the purpose of the Feasibility Study, which states: *"The purpose of the Feasibility Study is to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."* The words *minimize* and *mitigate* are incongruous with

the words *improving* and *restoring* as they related to change to aquifer levels or stream flow in the Sequalitchew Creek watershed. Alternative 2.1.6 further degrades the natural functioning of Kettle, seep and Edmond Marsh wetlands, diminishes flow in Sequalitchew Creek and infiltrates commingled physically and chemically altered groundwater and polluted stormwater runoff into the groundwater that feeds pristine Puget Sound Springs, the latter of which flows onto a shoreline of state wide significance.

Alternative 2.1.5 Infiltrate Dewatering Water within the Mine is no longer being consider because: *"This alternative was determined to be infeasible by consensus of the parties to the memorandum of understanding."* [Page 76, lines 16 -17] How then can infiltrating stormwater runoff from 177 acres of manufacturing and industrial facilities built on impervious Olympia Bed soils and 8.3 cubic feet per second of discharging groundwater within the mine be judged as feasible when Alternative 2.1.5 which was judged by the parties to the memorandum of understanding as *infeasible*?

Alternative 2.1.6 would involve: *"…design, permitting, and construction of 1,000 feet of tightline pipe 1,250 feet of ditch, and a 0.5-acre to 5.4-acre infiltration pond…" "Water quality pre-treatment may be necessary depending on whether the groundwater system also intercepts stormwater."* It is highly unlikely that stormwater and groundwater can be kept separate. 8.3 cubic feet per second of discharging groundwater, containing fine grained particulate matter, would emanate from the exposed east sloped wall of the excavated South Expansion Area. This wall face will be exposed to the same precipitation falling on the impervious Olympia Bed soil at the bottom of the pit. Discharging groundwater, sediment from stormwater exposed and eroding sloped mine walls and runoff from impervious surfaces collected in drainage ditches would make segregation of groundwater discharge and stormwater runoff highly unlikely, if not impossible. Therefore, the entire combined flow of 8.3 cfs of groundwater and stormwater runoff from 177 acres would have to be treated to remove sediment and pollutants before being conveyed to infiltration ponds lest the buildup of fine-grained particulate matter negate the ability of the ponds to infiltrate the water. As far as using this water to recharge Puget Sound Springs is concerned there is no cost-effective treatment available to remove soluble pollutants (e.g., nutrients, heavy metals, organic compounds) from infiltrating surface water runoff. They will pass unaltered to contaminate the diminished groundwater supply of the Puget Sound Springs.

*"Planning, design, permitting, and construction of this alternative is anticipated to cost…between $900,000 and $1,200,000 if all mine stormwater, dewatering, and post-mining groundwater discharge is infiltrated. The higher costs also include construction of 5.5 acres of wetland mitigation."* Missing from this cost analysis is the costs to the City of DuPont (and its manufacturing, industrial, and residential property owners in the form of surface water management fees) of on-going (in perpetuity) operation, maintenance and eventual replacement of these surface water management facilities. Construction of 5.5 acres of wetland mitigation is incongruous with the stated purpose of the Feasibility Study, i.e., *"… to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."* Constructed wetland seldom provides the natural function and value of the destroyed wetlands that

they are supposed to mitigate. Constructed wetlands are seldom self-sustaining and require on-going maintenance (in this case by the City of DuPont) if they are to provide essential wetland function and value. The assumption that 5.5 acres of constructed wetlands in the midst of a manufacturing and industrial complex, or for that matter in the midst of a residential area, will adequately mitigate the elimination of Kettle and Seep wetlands, further degradation of 135 acre Edmond Marsh and a reduction in the base flow of lower Sequalitchew Creek borders on the ludicrous.

*"Some ongoing monitoring and maintenance would be required to ensure continued function of the conveyance and infiltration* [and the 5.5-acre constructed wetland] *system. Maintenance would include periodic inspection of the tightline and weir, removal of any accumulated debris, and removal of accumulated sediment from the infiltration pond* [and a 5.5 acre constructed wetland since it would not be self-sustaining]. What funding source is proposed to cover the costs to the City of DuPont for ongoing operation, maintenance and replacement of these facilities? CalPortland will be long gone from the scene.

*"Groundwater would be segregated from stormwater and would be infiltrated back into the ground. No detectable change in overall water quality is anticipated."* It is naive to believe that no detectable change in overall water quality will occur as a result of implementing what is proposed in 2.1.6. As mentioned above it is highly unlikely, if not impossible, to segregate 8.3 cfs of groundwater flowing out of the east wall of the mine onto the floor of the mine from precipitation falling on this same wall and on 177 acres of impervious Olympia Bed soil. The infiltration of this combined water through a 5 (as CalPortland has suggested) or 25 feet (as the current mining permit dictates) of underlying pervious course grained gravel (assuming that this water is conveyed away from the area underlain by Olympia Bed soil) is going to impact the quality and quantity of groundwater discharging into Puget Sound via the Puget Sound Springs.

*"If all the mine stormwater, and temporary and post-mining groundwater discharges are infiltrated, this alternative would have similar effects as construction of North Sequalitchew Creek would have…on the flow regime in the upper reach of the Sequalitchew Creek Ravine, marshes, and aquifer levels.* The adverse *effects* referred to above were grounds for the Environmental Coalition to conclude that the North Sequalitchew Creek alternative was fatally flawed. I believe that the Environmental Coalition should, for the same reasons, conclude that Alternative 2.1.6 is fatally flawed.

In regard to sustainability: *"This* [2.1.6] *alternative would require a modest level of ongoing maintenance to keep the passive dewatering system functioning smoothly. The key to sustainability is providing adequate water quality treatment to avoid impacting the long-term function of the infiltration pond. The type of water quality pre-treatment necessary would depend on whether the collection system also intercepts stormwater."* I would disagree with the word *modest.* As mentioned previously a surface water management system that complies with NPDES requirements for the discharge of surface water runoff (discharging groundwater now on the surface being a component thereof) by infiltration into an underlying aquifer and thence to Puget Sound and the operation,

maintenance and requirement for the periodic replace of the requisite facilities to handle the quantity of water described herein will overwhelm the very limited financial capacity and staff of the City of DuPont.

**Is Alternative 2.1.6 Fatally Flawed?**

I believe so.

Alternative 2.1.6 has an in perpetuity adverse environmental impact on the groundwater hydrology of the Sequalitchew Creek watershed and its groundwater dependent springs (including Puget Sound Springs), wetlands and Sequalitchew Creek and an in perpetuity adverse on-going financial impact on the City of DuPont and its citizens.

Unfortunately, the Memorandum of Understanding/Feasibility Study process proposed and managed by CalPortland has focused on mitigating the adverse environmental impacts that dewater the Vashon aquifer will have on the function and value of an already degraded Edmond Marsh and Sequalitchew Creek. Its motivation is to increase its take of gravel from the South Expansion Area where the gravel is now saturated by the Vashon aquifer. CalPortland has offered fish population enhancement via a proposed North Sequalitchew Creek to gain support for this alternative by the Nisqually Tribe and the Washington Department of Fish and Wildlife. If fish population enhancement is the goal of the Nisqually Tribe and the Washington Department of Fish and Wildlife then I submit that they need to support alternatives that enhanced discharge of Vashon aquifer groundwater discharge into and through Edmond Marsh and down Sequalitchew Creek Canyon and oppose Alternative 2.1.6 which will infiltrate a ground/storm water blend of polluted water that will degrade the quality and quantity the water of Puget Sound Springs which discharge onto critical and sensitive near shore habitat that is vital to salmon recovery.

The interests of the citizens of the City of DuPont have been poorly represented during the entire MOU/FS process. Citizens have been relegated the role of spectators with their opportunity to participate limited to 15 minutes at the conclusion of FS meetings. Yet it is the citizens of DuPont whose property values, quality of life and surface water management fees are going to be most impacted by the decisions that are made by CalPortland, Environmental Coalition and governmental agency representatives. Unfortunately the City Manager, City Attorney and members of City staff have not acted in the best interests of the citizens of DuPont otherwise they would have applied and enforced the City's critical and sensitive area ordinances at the time that CalPortland applied for a Conditional Use Permit that allowed dewatering of the Vashon aquifer.

In the final analysis all the Alternatives that have been proposed and considered by the participants in the MOU/FS process that allow dewatering of the Vashon aquifer are fatally flawed if the purpose of the process is: *…to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."*

**Attachments:** CALPORTLAND'S SEQUALITCHEW CREEK RESTORATION PLAN.docx; AN EXAMINATION AND EVALUATION OF ALTERNATIVE 2.1.6.docx

Renee,

I have again attached a copy of my summary of the disastrous outcome of the "process" that all parties to the 2011-2012 Settlement Agreement elected to follow.

The feasibility study phase of that process gave birth to the Infiltrate breached Vashon aquifer groundwater discharging out of the steep Southeastern slope of the mine commingled with surface water runoff from a light industrial/residential village into the mine pit floor.

I responded to that fallacious proposal at the time. See the second attachment to this email.

The CalPortland mined out pit will become the City of DuPont's worst ever nightmare.

An effective Chambers-Clover Watershed Council along with an active and engaged DuPont citizenry could have prevented what is now likely to happen as a result of an anemic FEIS response prepared by DuPont hired consultants.

There is still a slim chance that CalPortland and the City of DuPont could develop a win-win beneficial future outcome for both parties if the Hearing Examiner is provided compelling evidence of glaring deficiencies in DuPont's FEIS document. So far I don't see that happening.

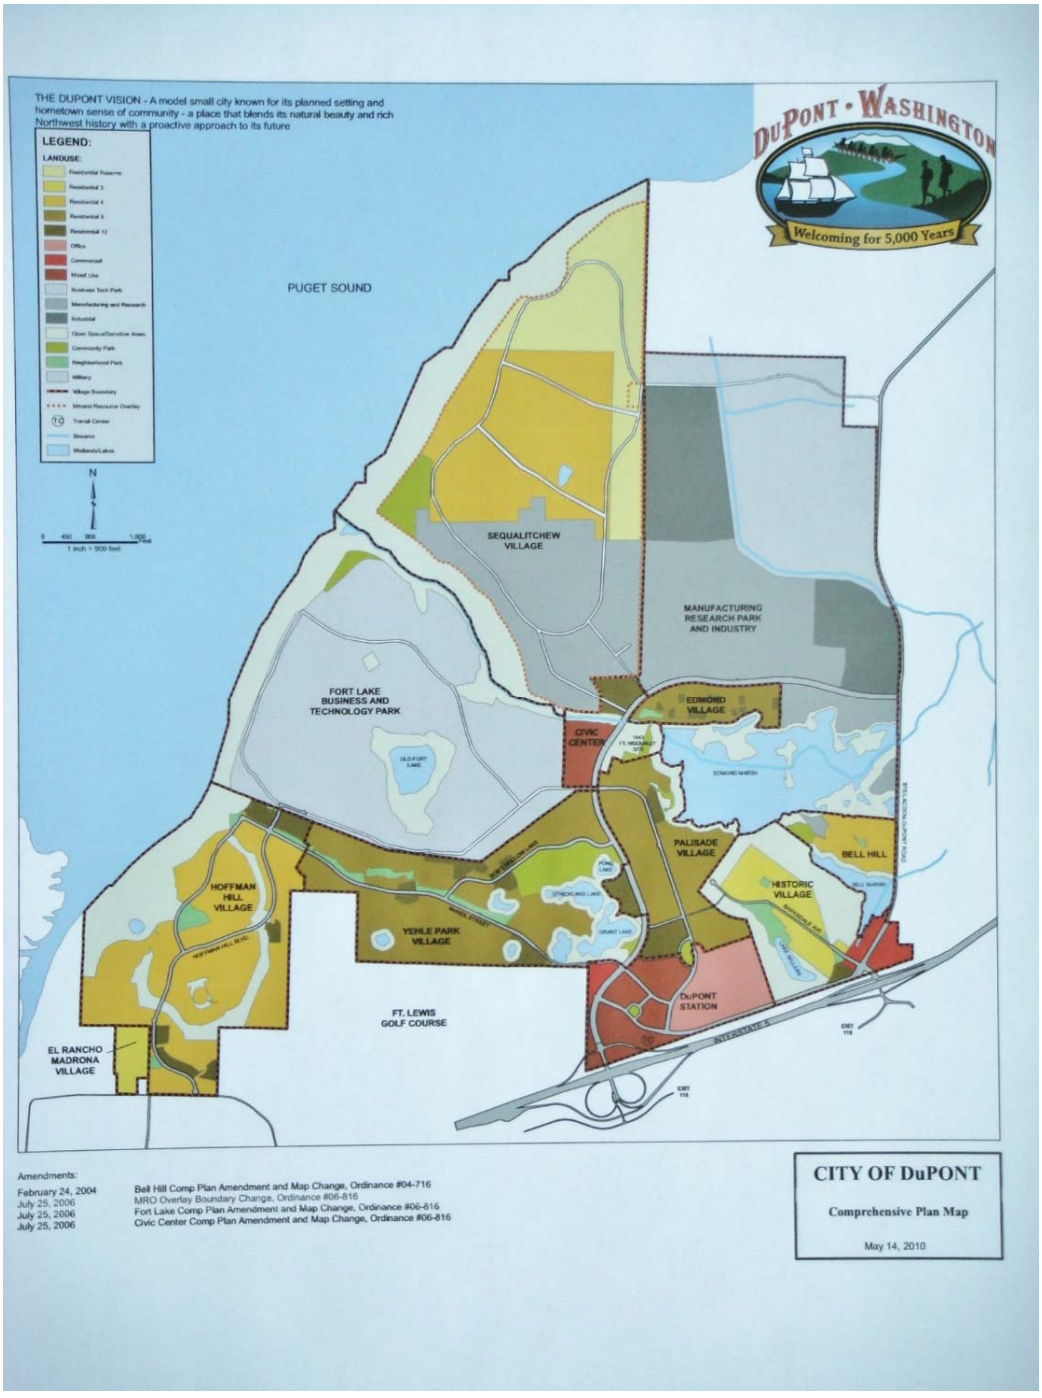
Don

# CALPORTLAND'S SEQUALITCHEW CREEK RESTORATION PLAN

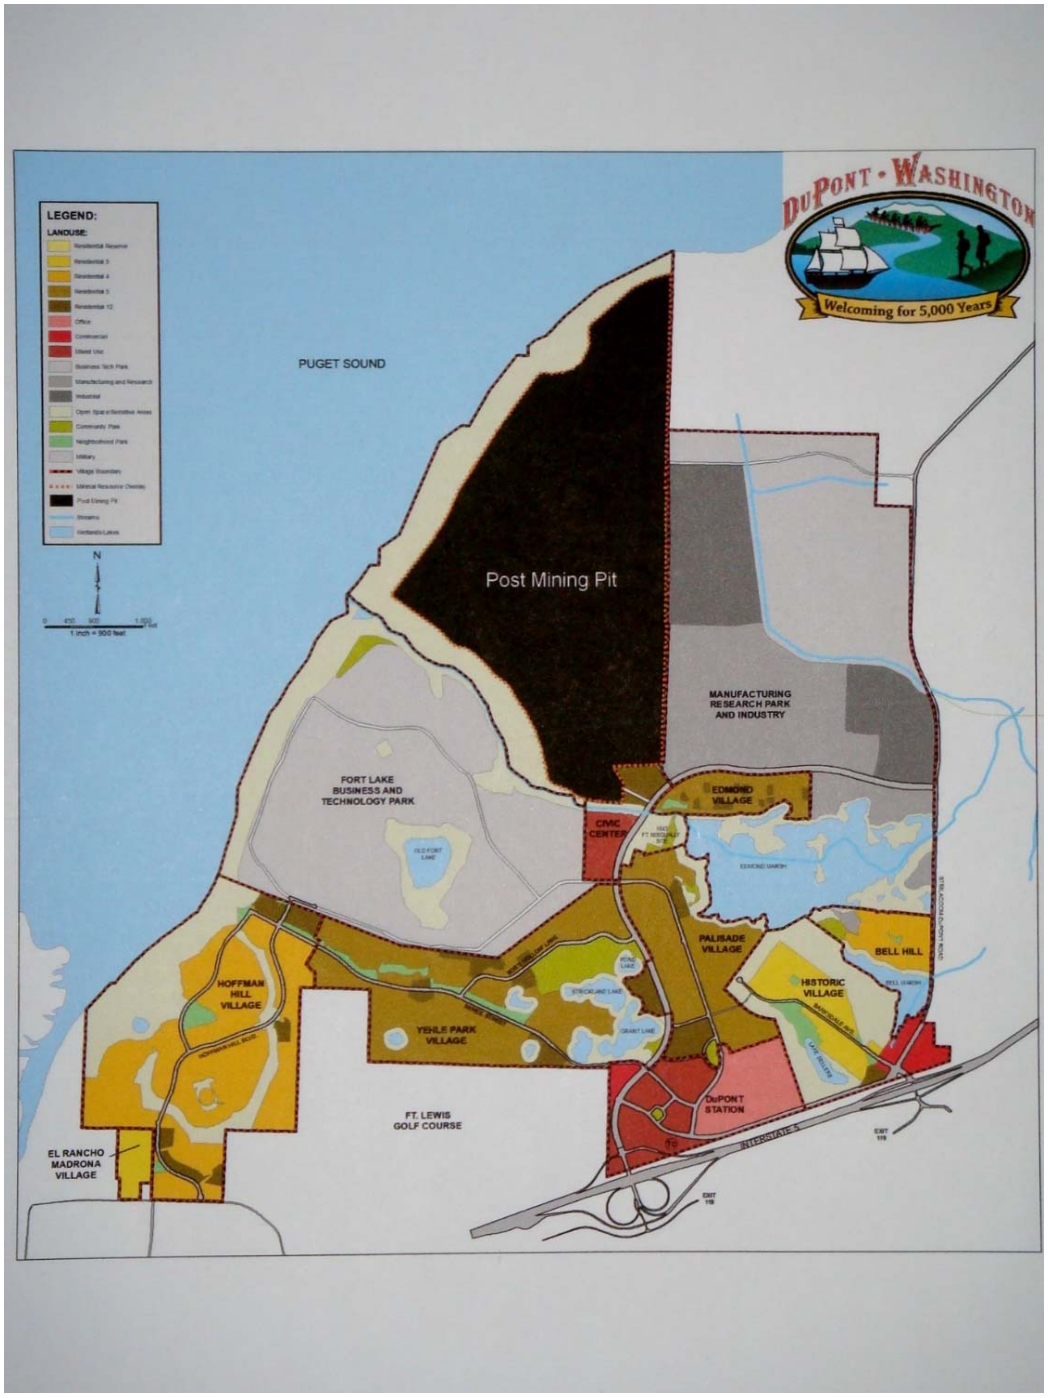
## Preface

This paper describes how Weyerhaeuser and CalPortland (under its several alias) have succeeded in manipulating events, data and people into accepting their version of the future of a once forested 700 acres of prime DuPont real estate.

## Weyerhaeuser's Vision as presented to DuPont's private property owners



**Weyerhaeuser/CalPortland's Vision of 700 acres of prime DuPont real estate**



**CalPortland's proposal for reconciling these two contrasting and contradictory visions**

In exchange for the City of DuPont issuing a conditional use permit to mine approximately 300 acres of Vashon aquifer groundwater saturated gavel contained within the footprint of its 700 acre gravel pit CalPortland has offered the City of DuPont a Sequalitchew Creek Restoration Plan that upon its implementation will render the site unfit for its intended future development.

**Origin of the Sequalitchew Creek Restoration Plan**

The CalPortland/Environmental Caucus/South Puget Sound Salmon Enhancement Group drafted Sequalitchew Creek Restoration Plan is the result of three decades of CalPortland's manipulation of events, data and people as chronicled below.

**1993 DuPont Quality-of-Life Committee Newsletter**

In June, 1993 a Neighbor to Neighbor citizen newsletter "*…dedicated to the great proposition that DuPonters have the right (and responsibility) to protect our quality-of-life and this region's historical and environmental integrity*" published an article in opposition to a proposed Weyerhaeuser/Lone Star DuPont 700 acre gravel mine.

The article is insightful since it described in detail Lone Star's (CalPortland) strategy for overcoming citizen opposition to its acquisition of a conditional use permit to mine gravel in land that it either leased or purchased in the City of DuPont under conditions that it dictated.

CalPortland's 1993 strategy was to provide DuPont's Planning Manager the necessary funding and consultants to draft a request that the City issue a conditional use permit to mine dry gravel in City designated mineral resource overlay areas and to convince the Mayor and City Council that approval of such a conditional use permit would benefit the City of DuPont. Should issuance of a conditional use permit to mine gravel be legally challenged by any outside party, i.e., citizens of DuPont or environmental advocacy group CalPortland would pay all the City's legal expenses necessary to defend the City Council's approval of issuance of a conditional use permit.

Application of this CalPortland strategy is manifest in all CalPortland manipulated events that have taken place since 1993. This strategy has been instrumental in determined the outcome of subsequent actions related to the development of the CalPortland/Environmental Caucus/South Puget Sound Salmon Enhancement Group drafted Sequalitchew Creek Restoration Plan. The Sequalitchew Creek Restoration Plan contains no relevant citizen stakeholder input.

Provisions of RCW 90.82 Watershed Planning assure that "*DuPonters have the right (and responsibility) to protect* [their] *quality-of-life and this region's historical and environmental integrity*" as codified below.

"*The purpose of this chapter is to develop a more thorough and cooperative method of determining what the current water resource situation is in each water resource inventory area of the state and to provide local citizens with the maximum possible input concerning their goals and objectives for water resource management and development.*" RCW 90.82.005

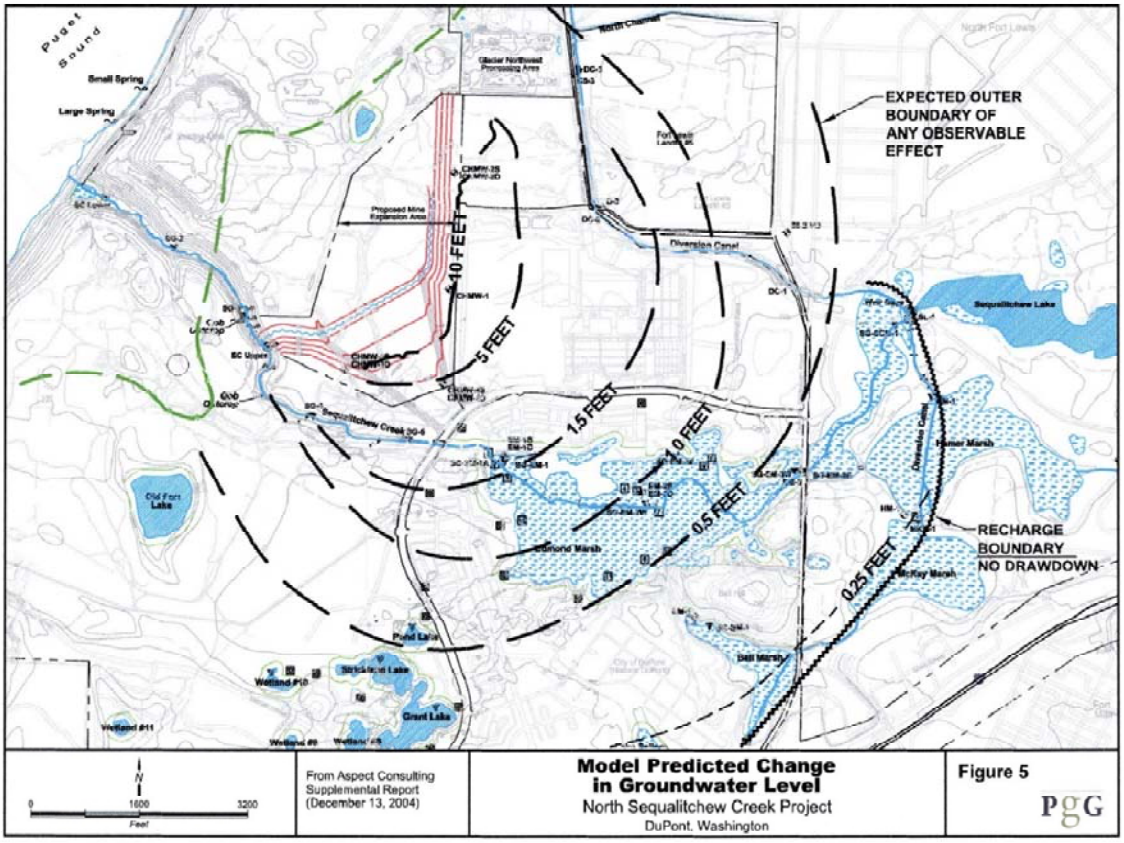
"*The local development of these plans serves vital local interests by placing it in the hands of people: Who have the greatest knowledge of both the resources and the aspirations of those who live and work in the watershed; and who have the greatest stake in the proper, long-term management of the resources.*" RCW 90.82.010

DuPonters have been denied "*the right (and responsibility) to protect* [their] *quality-of-life and* [DuPont's] *historical and environmental integrity*" contrary to provisions of RCW 90.82.

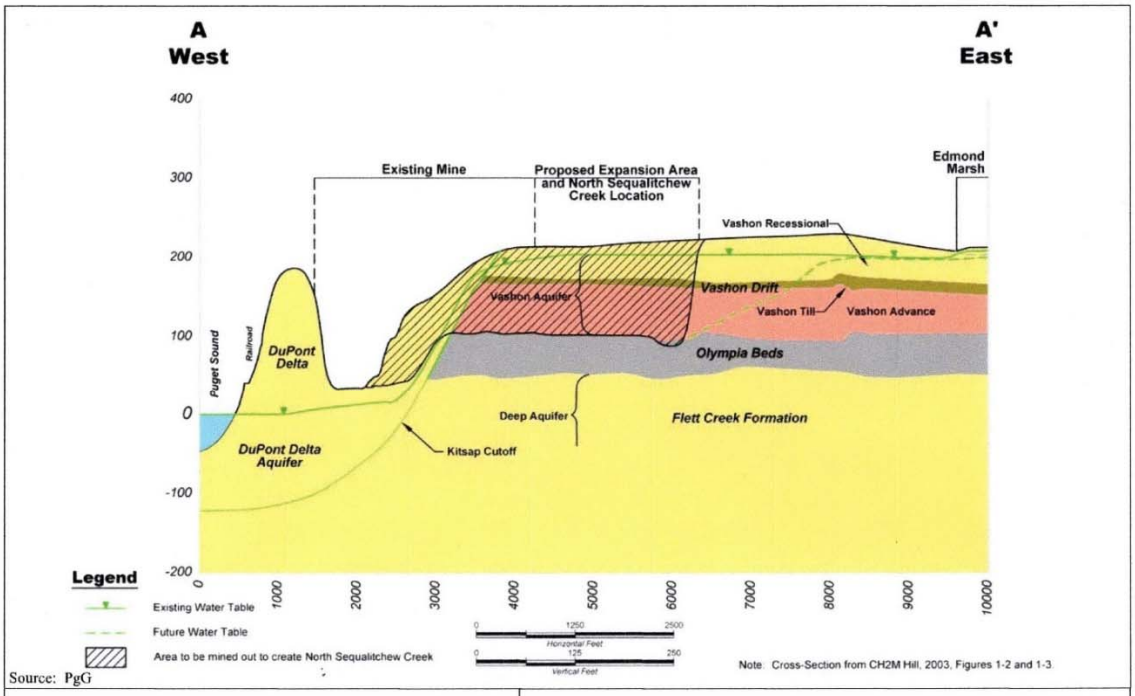
**The 1994 Settlement Agreement**

In 1994 in exchange for limited access and use of Weyerhaeuser owned land the City and several environmental advocacy groups (Environmental Caucus) entered into an Agreement that granted Lone Star (CalPortland) a conditional use permit to mine gravel in a 360 acre designated mineral resource overlay area. A key provision of that Agreement was "*WRECO and Lone Star agree to seek no permit in the future to mine…in a manner that would significantly impact the flow of Sequalitchew Creek.*"

During 2002-2006 Glacier Northwest (CalPortland) employed several consulting firms to study the hydrogeology of its existing 360-acre gravel mine and a proposed 170 acre south expansion area of its mine. The task was to come up with a plan (North Sequalitchew Creek) to access the Vashon aquifer saturated gravel that existed in 117 acres of its existing mine and in 170 acres of a leased south mine expansion area. These two areas were jointly referred to as the South Parcel.



The results of CalPortland consultants' studies are shown in the above illustration, i.e., a ground and surface water drainage ditch constructed at the base of the southeastern wall of the south mine expansion area. This in mine drainage ditch was intended to discharge its comingled groundwater and stormwater runoff through a cut in the southwestern mine wall and into lower Sequalitchew Creek. This proposal was called the North Sequalitchew Creek project.



This figure is from the Final Supplemental Environmental Impact Statement, Glacier Northwest DuPont Mining Area Expansion and North Sequalitchew Creek Project, May 1, 2007, Figure 3.4-1

**Figure 9**
**Generalized Geologic Cross Section**

553-3044-001/03(04) 1/09 (B) ai

The above illustration shows the location of the proposed in mine breached Vashon aquifer groundwater and stormwater runoff interceptor drainage ditch (aka North Sequalitchew Creek) perched upon impervious post mining exposed Olympia Bed material (center of the illustration). Note also that the post mining condition exposes impervious Olympia Bed material westward to a 25 foot drop off into the pervious bottom of the existing CalPortland DuPont mine.

**Expansion of DuPont's mineral resource overlay area**

In 2006 CalPortland persuaded the DuPont City Council to designate the entire 700 area shown in black on the second iteration of DuPont's Comprehensive Plan Map as a mineral resource overlay area. It included the South Parcel and a CalPortland owned North Parcel.

**2006-2008 The City of DuPont modifies its Comprehensive Plan**

The modification was done to reflect the expanded mineral resource overlay area and facilitate the permitting of Glacier Northwest's mining of both the South and North Parcels.

**2008 Nisqually Delta Association Intervention**

On July 16, 2008 the Nisqually Delta Association asserted that the proposed expansion of Lone Star's (CalPortland) gravel mine violated section II.B.5 of the 1994 Settlement Agreement's provision "…*not to seek any permits to mine within the shoreline jurisdiction, within 100 feet of*

*the top of the bank of Sequalitchew Creek, or in a manner that would significantly impact the flow of Sequalitchew Creek.*"

On January 4, 2009, the Nisqually Delta Association sent a Notice of Breach of the 1994 Settlement Agreement and Request for Mediation to Glacier Northwest and the City of DuPont.

**February 13, 2009 Don Russell submittal to DuPont's Hearing Examiner**

In my submittal I expressed opposition to the City's issuing a conditional use permit to Glacier Northwest for mining the South Parcel as proposed by Glacier Northwest's consultants and as conditioned by DuPont's Planning Manager on several bases.

Glacier Northwest's proposal envisioned the creation of an in mine 4000 foot long drainage ditch (aka North Sequalitchew Creek) to intercept 6.5 million gallons per day of breached Vashon aquifer groundwater discharging from the face of the steep eastern bank of the expanded South Parcel gravel mine plus any stormwater runoff from 287 acres of exposed South Parcel Olympia Bed impervious surface. This comingled discharging groundwater and polluted surface water runoff would then be conveyed through 500 feet of pipeline bored through the south wall of the mine and discharge into the Sequalitchew Creek ravine. Above this point of discharge there would be no groundwater discharge supplied base flow in Sequalitchew Creek.

I noted that execution of the proposed North Sequalitchew Creek plan would result in the elimination of Kettle Wetland and Sequalitchew Creek canyon Seep and Riparian Forest wetlands in violation of several of DuPont's sensitive areas regulations and RCW 78.44 that states "*…reclamation of mined lands is necessary to prevent or mitigate conditions that would be detrimental to the environment and to protect the general welfare, health, safety, and property rights of the citizens of the state.*" The post mining condition of a dewatered DuPont gravel mine would be in violation of provisions of this RCW mandate.

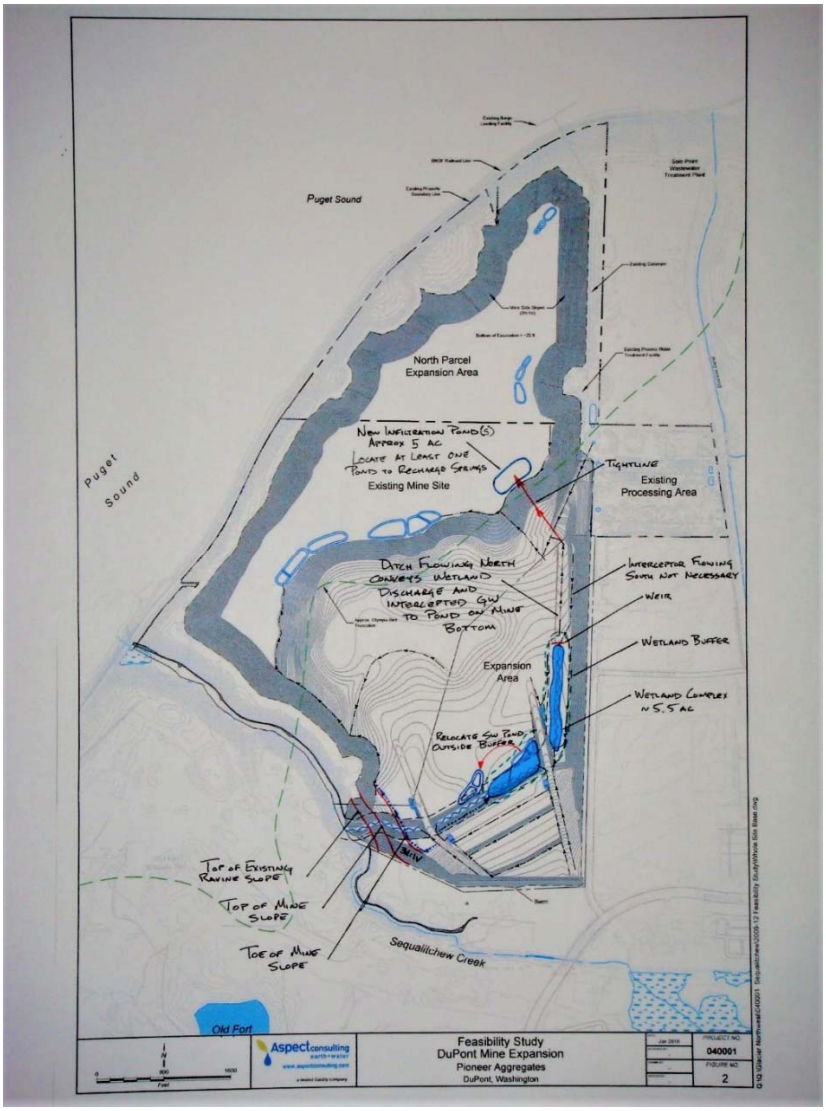
Subsequently a decision was made by the parties signatory to the 1994 Settlement Agreement to abandon the Hearing Examiner approach to resolving the dispute between the Nisqually Delta Association, Glacier Northwest (CalPortland) and the City of DuPont in favor of what became known as the Memorandum of Understanding/Feasibility Study process.

**Memorandum of Understanding/Feasibility Study process**

In 2010 CalPortland proposed that the concerned parties enter into a Memorandum of Understanding Agreement. This CalPortland drafted MOU Agreement contained the following provisions: (1) *This MOU reflects the parties understanding of the process that will be followed in an effort to avoid protracted litigation concerning the 1994 Settlement Agreement.* (2) *The purpose of the Feasibility Study will be to identify and evaluate potential alternatives for improving ecosystem functions in the Sequalitchew Creek's watershed. The parties expressly recognize that mine dewatering is one such an alternative*, and (3) *The parties will meet to develop a list of possible actions that would mitigate the potential impacts of the proposed project by improving, enhancing, or protecting ecosystem functions in the Sequalitchew Creek watershed*.

On February 2, 2010 I advised DuPont City Council to not enter into such an MOU/Feasibility Study Agreement on the basis that the CalPortland proposed North Sequalitchew Creek South Parcel mining proposal, if executed, would violate several DuPont sensitive area regulations and the post mining restoration provisions of RCW 78.44, as would any other dewatering proposal.

All of the identified and evaluated potential alternatives for improving ecosystem function in the Sequalitchew Creek watershed were fatally flawed. Nevertheless, one alternative was chosen as a result of the MOU/FS process. It was alternative 1.6 titled: Infiltrate a Portion of Dewatering and Post-mining Groundwater Discharge to Recharge Puget Sound Springs.



Derek Booth of Stillwater Sciences, consultant for the Environmental Caucus, described alternatives that proposed infiltration of dewatering water within the mine as: "*We find no basis to expect they will offer any net environmental gain and do not support their advancement.*"

I submitted a paper titled The Consequence of Dewatering the Vashon Aquifer to all parties to the MOU/FS Agreement that stated that the 1.6 alternative was more seriously flawed than was the original CalPortland proposed North Sequalitchew Creek dewatering proposal.

In September 2010 Ron Frederick requested that Mayor Jenkins form a citizen advisory group to advise the Mayor and City Council regarding growing citizen concern about CalPortland's undue influence on DuPont's Planning Manager and Hearing Examiner, the lack of application and enforcement of existing City of DuPont's sensitive area regulations, and the very limited opportunity afforded citizens to participate in the ongoing CalPortland/Environmental Caucus/City watershed planning process.

**2011 Settlement Agreement**

On June 24, 2011 Sally Toteff (DOE), Pete Stoltz (CalPortland) and Tom Skjervold (Nisqually Delta Association) announced "**Agreement reached on plan to help restore Sequalitchew Creek, allow new mining proposal."** This Agreement essentially removed most of the constraints to CalPortland's obtaining a permit to mine dry (North Parcel) and Vashon aquifer groundwater saturated gravel (South Parcel) from CalPortland's expanded (from 360 acres under provision of the 1994 Settlement Agreement to 700 acres under provisions of the 2011 Settlement Agreement) DuPont gravel mine.

I advised DuPont Council members in numerous papers (one of which was titled: Grounds for Not Approving the Settlement Agreement) and via public testimony that the City should not become a signatory to the 2011 Settlement Agreement for a variety of reasons. All of which would significantly reduce the City's ability to bargain with CalPortland for significant benefits that would accrue to DuPont's residents, private property owners, visitors, and tourists.

On January 26, 2012, the City of DuPont Council authorized Mayor Grayum to sign on behalf of the City of DuPont the CalPortland lawyer drafted 2011 Settlement Agreement.

**Sequalitchew Creek Restoration Plan**

The 2011 Settlement Agreement required that the Sequalitchew Creek Restoration Plan incorporate the below five elements (as defined by CalPortland's consultants Aspect and Anchor) in order for the Plan to be approved by CalPortland and the Environmental Caucus.

*4.1.1. Improvement of gradients so* [surface] *water discharges from Hamer and Bell Marshes flow into Edmond Marsh rather than into the diversion canal.*

*4.1.2. Improvements to create significant* [surface water] *flows from Sequalitchew Lake into the Edmond Marsh complex to support a functional creek ecosystem, and provide for the passage of migratory fish in the Sequalitchew Creek system. To achieve this goal, the Parties will consider, at minimum, modification of the diversion canal flood control structure and gradients.*

*4.1.3. Rehabilitation of Edmond Marsh by removal of sufficient fill and other flow impediments to provide the hydraulic gradients and capacity necessary to achieve and maintain adequate* [surface water] *flows through the Marsh.*

*4.1.4. Rehabilitation of Sequalitchew Creek below Edmond Marsh to reduce seepage, improve fish habitat, and help restore year-round* [surface water] *flows.*

*4.1.5. Active management of beaver activities to maintain the hydraulic gradients that provide* [surface water] *flows through Hamer, Bell, and Edmond marshes. For purposes of this section, "active management of beaver activities" means management commencing with the least intrusive method and progressing to more intrusive methods only as necessary to maintain hydraulic gradients and flows, with lethal removal utilized only as a last resort.*

The above inserted bracketed words make it clear that CalPortland incorrectly assumed that Sequalitchew Creek is a surface water driven system. It is not. It is a groundwater discharge driven system. Herein lies the fallacious foundation of the CalPortland consultant drafted Sequalitchew Creek Restoration Plan.

Unfortunately, these CalPortland consultant prescribed elements were never vetted by others to determine whether or not they were grounded in a proper characterization of the 2011 condition of the Sequalitchew Creek watershed. What existed then (on the left) and what exists now (on the right) is best illustrated by a comparison of the two below photographs. In stream flows are dependent upon shallow aquifer groundwater levels. Ground water withdrawals (dewatering) are antithetical to surface water flow in the Edmond Marsh/Sequalitchew Creek ecosystem.

CalPortland's consultants characterized the Sequalitchew Creek/Edmond Marsh complex as a surface water driven system. It is not. It was a groundwater driven system that over the years has been adversely impacted by ever declining Vahon aquifer groundwater levels and ever increasing quantities of stormwater runoff being discharged into this once pristine salmon bearing groundwater fed stream and associated wetland complex.

What CalPortland's consultants monitored during the period from 2003 up until till 2011 and upon which the Sequalitchew Creek Restoration Plan was built no longer represents the condition of the Sequalitchew Creek watershed today. The Sequalitchew Creek Restoration Plan proposed by CalPortland's consultants is not relevant to addressing today's degraded condition of Edmond Marsh and what little is left of a naturally flowing and functioning Sequalitchew Creek.

**A Relevant Sequalitchew Creek Restoration Plan**

A relevant Sequalitchew Restoration Plan would recognize that a further and permanent lowering of the Vashon aquifer groundwater level beneath the Edmond Marsh/Sequalitchew Creek complex as proposed by CalPortland's dewatering proposal is antithetical to restroration of a groundwater discharge fed salmon bearing Sequalitchew Creek flowing through an associated groundwater sustained Edmond Marsh wetland.

The elements of such a plan would be the control of the surface water levels of upgradient groundwater fed, occasionally stormwater runoff polluted, Bell, McKay and Hamer Marshes so as to provide the necessary hydraulic head to cause water contained in these marshes to infiltration into the underlying groundwater that flows subsurface (not on the surface) to discharge into lower elevation level Edmond Marsh.

To facilitate the interception of this subsurface flow of groundwater and enhance the volume of its discharge into Edmond Marsh a Sequaltichew Creek channel should be constructed (dug) all along the eastern boundary of Edmond Marsh by CalPortland. This is the proper location for constructing a discharging Vashon aquifer groundwater intercepor channel, not at the bottom of a breached Vashon aquifer groundwater discharge/stormwater runoff flooded gravel mne pit!

**Action Required**

The Mayor and City Council should start acting on behalf of the citizens of the City of DuPont that they represent instead of acceding to CalPortland's under threat of "*protracted litigation*" demands.

The proposed Sequalitchew Creek Restoration Plan offered by CalPortland is a bright and shiny bauble to attract attention away from the fact that its execution will cause permanent and irreversible environmental harm to a groundwater disconnected Edmond Marsh/Sequalitchew Creek complex and a lost opportunity for what could become a salmon bearing Sequalitchew Creek flowing through the center of the City of DuPont.

If the proposed CalPortland Sequalitchew Restoration Plan is executed not only will Edmond Marsh/Sequalitchew Creek be lost forever, DuPont private property owners will be paying to operate and maintain an in mine facility to handle 6.5 million gallons per day of discharging groundwater comingled with a like quantity of polluted stormwater runoff in an area designated by the City to become Sequalitchew Village residential and industrial area real estate.

**Conclusion**

I have written and circulated numerous papers on the proper characterization of the Edmond Marsh/Sequaltichew Creek complex, how Mother Nature intended this complex to work, how the actions of humans have impaired its natural function, almost beyond the ability to restore it, and, importantanly, how at this late date this complex can be restored as desirable salmon habitat, an aesthetic ammenity to be enjoyed by the citizens of DuPont, and a popular tourist destination.

September ?, 2011 Gendler and Mann (attorneys) letter to Mayor Jenkins and City Council stating: *"You may believe that the Settlement Agreement does not bind you to any specific course of action and that you may therefore approve it prior to your review of the SEPA analysis. This belief is wrong for at least two significant reasons. First and foremost, ask yourselves the simple questions - if the Settlement Agreement does not bind the City to any course of action, then why are you signing it? Why does CalPortland want you to sign it? The answer should be obvious -by committing itself to the Settlement, the City is giving at least the appearance of cooperation and that it will issue the future permits. Indeed, the Settlement Agreement confirms in Section 12 that "based on existing information and analysis the Governmental parties believe they can issue permits consistent with this agreement." But the City is not in "believe" that permits may be issued for this project - especially at this early date. The City owes to itself and its citizens the responsibility and duty to remain absolutely and completely neutral.*" The letter went on to state: "*The City should decline to participate in the Settlement. The City should instead follow the process set out by SEPA and its implementing regulations, and, prior to making any decisions on CalPortland's proposal, fully educate itself on the complete environmental ramifications of your decisions.*"

September 6, 2011 DJR Power Point presentation titled Hydrology and Geology of DuPont.

September 27, 2011 DJR addresses the Mayor and City Council expressing opposition to the City signing the 2011 Settlement Agreement since it would commit the City staff to support CalPortland's quest to dewater and mine the South Parcel. That address is documented in a paper titled Public Hearing Comments on the 2011 Settlement Agreement.

September 30, 2011 DJR Power Point presentation titled Commentary on Settlement Agreement

October 2, 2011 Diana Barbera Letter published in The Suburban Times bearing the title DuPont Resident opposes [2011 Settlement] agreement.

January 26, 2012 paper titled Final Comments on the 2011 Settlement Agreement citing reasons why the City Council should not authorize the Mayor to become a signatory to the 2011 Settlement. It concluded by stating: "*…the role of the DuPont City Council should be to preserve, protect, restore and enhance the wellbeing, property values and quality of life for the citizens of DuPont by not approving the 2011 Settlement Agreement which promotes the commercial interests of CalPortland whose expanded South Parcel mining activities would diminish the value of all that the citizens of DuPont cherish about their City.*"

On January 26, 2012, the City Council voted in favor of authorizing the Mayor to sign the 2011 Settlement Agreement that pledged the City to support CalPortland's 1994 to 2011 quest to obtain a permit to dewater and mine the South Parcel.

January 29, 2012 DJR submits a Letter to the Editor of The Suburban Times under the banner The Consequence of the City of DuPont Council Approving the 2011 Settlement Agreement. That article concluded with the statement: "*There is no mitigation that will offset the adverse impacts that lowering the groundwater level in DuPont to facilitate mining saturated gravel in 117 acres of CalPortland's existing mine and in 180 acres of a leased south expansion area collectively known as the South Parcel will have on the natural function of Edmond Marsh, Sequalitchew Creek, Kettle Lake (to be eliminated), Sequalitchew Creek Ravine Riparian Forest and Springs and Puget Sound Shoreline Springs all of which are dependent upon their connectivity to and continuity with Vashon aquifer groundwater.*"

What followed in subsequent years was CalPortland's consultants (Anchor and Aspect), Nisqually Delta Association (Tom Skjervold) and South Puget Sound Salmon Enhancement Group (Lance Winecka) discussions on how to implement provisions of CalPortland lawyers' crafted 2011 Settlement Agreement. These discussions were closely held, resulting in precluding any DuPont citizen and concerned watershed stakeholder input. What emerged from these discussion was the CalPortland consultant crafted Sequalitchew Creek Restoration Plan.

In 2017 I provided the City of DuPont a proposed City managed Edmond Marsh/Sequalitchew Creek restoration plan. This plan was based upon a proper characterization of the condition of the Edmond Marsh and Sequalitchew Creek ecosystem. It was titled Edmond Marsh Fact vs [CalPortland's] Fiction.

Bottom line: CalPortland's proposed Vashon aquifer dewatering interception channel should be constructed by CalPortland paralleling the eastern shoreline of Edmond Marsh and be named coho salmon friendly groundwater fed Sequalitchew Creek and its off channel associated Edmond Marsh wetlands. It should not be located at the bottom of a mined out gravel pit that is subsequently slated to be developed as Sequalitchew Village (featuring Kettle Lake) and light industrial park that does not experience, in perpetuity, continuous groundwater discharge exacerbated by intermittent stormwater runoff flooding events.

## AN EXAMINATION AND EVALUATION OF ALTERNATIVE 2.1.6

### Preface

This paper examines and fatal flaw evaluates Alternative 2.1.6 Infiltrate Stormwater and Groundwater Discharges to Recharge Puget Sound Springs. It does so by reciting passages from the March 25, 2010 Draft Feasibility Study (in italics), providing evaluation commentary (in this print format) and offers a conclusion regarding its fatal flaw status.

### Relevant Passages and Commentary

*"The purpose of the Feasibility Study is to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."*

*"…surface water features within the Sequalitchew Creek basin are hydraulically connected and interact with the groundwater system."*

*"It is these mingled Vashon Aquifer and sea level aquifer waters that form the Puget Sound shoreline springs, referred to as the Large and Small Springs north of the mouth of Sequalitchew Creek."*

*"Groundwater discharges as springs and seeps in the lower Sequalitchew Creek…and provides the majority of creek baseflow which varies between approximately 0.5 cubic feet per second (cfs)(summer) and 1.5 cfs (winter).* Dewatering the Vashon aquifer and excavating gravel in the South Expansion Area at or below the elevation of the adjacent Sequalitchew Creek bed will cause diminishment or cessation of base flow in Sequalitchew Creek. This is clearly a violation of the no impact provision of the 1994 Agreement.

*"The post-mining groundwater discharge is predicted to average about 7 cfs and range seasonally from 6 to 9 cfs."*

*"A 1.78-acre kettle wetland is located in a large, closed depression that lies near the center of the existing mine site. The kettle wetland vegetation communities are relatively susceptible to changes in groundwater hydrology, which directly control water levels in the wetland."* Alternative 2.1.6 would eliminate this Class 2 wetland. Such an act would be in violation of a provision (25 foot buffer) of CalPortland's current mining permit and the City of DuPont's municipal code DMC 25.105.070.1(f).

*"West Edmond Marsh is an approximate 135-acre wetland with a hydraulic regime dominated by surface water inputs to the south and east."* Alternative 2.1.6 would impact this Class 1 wetland by lowering the groundwater level 1.5 feet beneath West Edmond Marsh. The City of DuPont's municipal code DMC 25.105.070.1(f) states that alteration of Class 1 wetlands is prohibited.

*"A 0.13-acre seep wetland complex of two long, very narrow, and non-contiguous wetlands is located just above the trail along Sequalitchew Creek at about RM 0.75 to 0.85."* Alternative 2.1.6 would disconnect this wetland complex from the groundwater source that sustains it. The elimination of this seep wetland complex would be in violation of DMC 25.105.070.1(f). Since the water that flows from this wetland discharges into Sequalitchew Creek such an act would be in violation of the 1994 Agreement.

*"The underlying zoning of the mine site is a mix of residential (North Expansion Area) and manufacturing and industrial (South Expansion Area) designations, and the mine is included within a mineral resources overlay. Mining activities are considered a temporary use and are consistent with the underlying zoning. Future land use is an important consideration in any alternative proposed for this study."* RCW 78.44.031(11) states that "Although both the need for and practicability of reclamation will control the type and degree of reclamation in any specific surface mine, the basic objective shall be to reestablish on a perpetual basis the vegetative cover, soil stability, and water conditions appropriate to the approved subsequent use of the surface mine and to prevent or mitigate future environmental degradation." 6 to 9 cubic feet per second of discharging groundwater emanating from the east sloping face of the South Expansion Area and flowing out onto exposed impervious Olympia Bed soil and its commingling with stormwater runoff poses an in perpetuity problem that neither industrial tenants or the City of DuPont should have to face. Such a scenario seems in clear violation of the basic objective of mine reclamation as cited in RCW 78.44.031(11). Furthermore, to convey this quantity of groundwater and commingled stormwater runoff to the central mine area and North Expansion Area for treatment and infiltration seems incongruous with the intended residential use of these areas of the spent mine as well.

*"Mining is permitted only above the aquifer and a 25-foot separation (10-foot separation for slopes) is required between mining activities and the seasonal high groundwater level. Stormwater is managed onsite through infiltration."* [Page 25, lines 19 – 22] This is a current restriction in CalPortland's aggregate mining permit. This restriction makes good environmental sense in that: *"…surface water features within the Sequalitchew Creek basin are hydraulically connected and interact with the groundwater system."* Alternative 2.1.6 would adversely impact the surface water features of Kettle, Seep and Edmond Marsh wetlands and Sequalitchew Creek since they are all hydraulically connected and interact with the groundwater system that CalPortland proposes to dramatically alter by dewatering the Vashon aquifer that sustains these critical and sensitive surface water bodies.

*"The goal of the alternatives in this section is to avoid, minimize, and/or mitigate any change to the aquifer levels in the project area. These alternatives would also avoid and minimize any change to the flow of Sequalitchew Creek from current levels."* [Page 28, lines 25 – 27] Note the subtle shift in the above language from that stated as the purpose of the Feasibility Study, which states: *"The purpose of the Feasibility Study is to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."* The words *minimize* and *mitigate* are incongruous with

the words *improving* and *restoring* as they related to change to aquifer levels or stream flow in the Sequalitchew Creek watershed. Alternative 2.1.6 further degrades the natural functioning of Kettle, seep and Edmond Marsh wetlands, diminishes flow in Sequalitchew Creek and infiltrates commingled physically and chemically altered groundwater and polluted stormwater runoff into the groundwater that feeds pristine Puget Sound Springs, the latter of which flows onto a shoreline of state wide significance.

Alternative 2.1.5 Infiltrate Dewatering Water within the Mine is no longer being consider because: *"This alternative was determined to be infeasible by consensus of the parties to the memorandum of understanding."* [Page 76, lines 16 -17] How then can infiltrating stormwater runoff from 177 acres of manufacturing and industrial facilities built on impervious Olympia Bed soils and 8.3 cubic feet per second of discharging groundwater within the mine be judged as feasible when Alternative 2.1.5 which was judged by the parties to the memorandum of understanding as *infeasible*?

Alternative 2.1.6 would involve: *"…design, permitting, and construction of 1,000 feet of tightline pipe 1,250 feet of ditch, and a 0.5-acre to 5.4-acre infiltration pond…" "Water quality pre-treatment may be necessary depending on whether the groundwater system also intercepts stormwater."* It is highly unlikely that stormwater and groundwater can be kept separate. 8.3 cubic feet per second of discharging groundwater, containing fine grained particulate matter, would emanate from the exposed east sloped wall of the excavated South Expansion Area. This wall face will be exposed to the same precipitation falling on the impervious Olympia Bed soil at the bottom of the pit. Discharging groundwater, sediment from stormwater exposed and eroding sloped mine walls and runoff from impervious surfaces collected in drainage ditches would make segregation of groundwater discharge and stormwater runoff highly unlikely, if not impossible. Therefore, the entire combined flow of 8.3 cfs of groundwater and stormwater runoff from 177 acres would have to be treated to remove sediment and pollutants before being conveyed to infiltration ponds lest the buildup of fine-grained particulate matter negate the ability of the ponds to infiltrate the water. As far as using this water to recharge Puget Sound Springs is concerned there is no cost-effective treatment available to remove soluble pollutants (e.g., nutrients, heavy metals, organic compounds) from infiltrating surface water runoff. They will pass unaltered to contaminate the diminished groundwater supply of the Puget Sound Springs.

*"Planning, design, permitting, and construction of this alternative is anticipated to cost…between $900,000 and $1,200,000 if all mine stormwater, dewatering, and post-mining groundwater discharge is infiltrated. The higher costs also include construction of 5.5 acres of wetland mitigation."* Missing from this cost analysis is the costs to the City of DuPont (and its manufacturing, industrial, and residential property owners in the form of surface water management fees) of on-going (in perpetuity) operation, maintenance and eventual replacement of these surface water management facilities. Construction of 5.5 acres of wetland mitigation is incongruous with the stated purpose of the Feasibility Study, i.e., *"… to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."* Constructed wetland seldom provides the natural function and value of the destroyed wetlands that

they are supposed to mitigate. Constructed wetlands are seldom self-sustaining and require on-going maintenance (in this case by the City of DuPont) if they are to provide essential wetland function and value. The assumption that 5.5 acres of constructed wetlands in the midst of a manufacturing and industrial complex, or for that matter in the midst of a residential area, will adequately mitigate the elimination of Kettle and Seep wetlands, further degradation of 135 acre Edmond Marsh and a reduction in the base flow of lower Sequalitchew Creek borders on the ludicrous.

*"Some ongoing monitoring and maintenance would be required to ensure continued function of the conveyance and infiltration* [and the 5.5-acre constructed wetland] *system. Maintenance would include periodic inspection of the tightline and weir, removal of any accumulated debris, and removal of accumulated sediment from the infiltration pond* [and a 5.5 acre constructed wetland since it would not be self-sustaining]. What funding source is proposed to cover the costs to the City of DuPont for ongoing operation, maintenance and replacement of these facilities? CalPortland will be long gone from the scene.

*"Groundwater would be segregated from stormwater and would be infiltrated back into the ground. No detectable change in overall water quality is anticipated."* It is naive to believe that no detectable change in overall water quality will occur as a result of implementing what is proposed in 2.1.6. As mentioned above it is highly unlikely, if not impossible, to segregate 8.3 cfs of groundwater flowing out of the east wall of the mine onto the floor of the mine from precipitation falling on this same wall and on 177 acres of impervious Olympia Bed soil. The infiltration of this combined water through a 5 (as CalPortland has suggested) or 25 feet (as the current mining permit dictates) of underlying pervious course grained gravel (assuming that this water is conveyed away from the area underlain by Olympia Bed soil) is going to impact the quality and quantity of groundwater discharging into Puget Sound via the Puget Sound Springs.

*"If all the mine stormwater, and temporary and post-mining groundwater discharges are infiltrated, this alternative would have similar effects as construction of North Sequalitchew Creek would have…on the flow regime in the upper reach of the Sequalitchew Creek Ravine, marshes, and aquifer levels.* The adverse *effects* referred to above were grounds for the Environmental Coalition to conclude that the North Sequalitchew Creek alternative was fatally flawed. I believe that the Environmental Coalition should, for the same reasons, conclude that Alternative 2.1.6 is fatally flawed.

In regard to sustainability: *"This* [2.1.6] *alternative would require a modest level of ongoing maintenance to keep the passive dewatering system functioning smoothly. The key to sustainability is providing adequate water quality treatment to avoid impacting the long-term function of the infiltration pond. The type of water quality pre-treatment necessary would depend on whether the collection system also intercepts stormwater."* I would disagree with the word *modest.* As mentioned previously a surface water management system that complies with NPDES requirements for the discharge of surface water runoff (discharging groundwater now on the surface being a component thereof) by infiltration into an underlying aquifer and thence to Puget Sound and the operation,

maintenance and requirement for the periodic replace of the requisite facilities to handle the quantity of water described herein will overwhelm the very limited financial capacity and staff of the City of DuPont.

**Is Alternative 2.1.6 Fatally Flawed?**

I believe so.

Alternative 2.1.6 has an in perpetuity adverse environmental impact on the groundwater hydrology of the Sequalitchew Creek watershed and its groundwater dependent springs (including Puget Sound Springs), wetlands and Sequalitchew Creek and an in perpetuity adverse on-going financial impact on the City of DuPont and its citizens.

Unfortunately, the Memorandum of Understanding/Feasibility Study process proposed and managed by CalPortland has focused on mitigating the adverse environmental impacts that dewater the Vashon aquifer will have on the function and value of an already degraded Edmond Marsh and Sequalitchew Creek. Its motivation is to increase its take of gravel from the South Expansion Area where the gravel is now saturated by the Vashon aquifer. CalPortland has offered fish population enhancement via a proposed North Sequalitchew Creek to gain support for this alternative by the Nisqually Tribe and the Washington Department of Fish and Wildlife. If fish population enhancement is the goal of the Nisqually Tribe and the Washington Department of Fish and Wildlife then I submit that they need to support alternatives that enhanced discharge of Vashon aquifer groundwater discharge into and through Edmond Marsh and down Sequalitchew Creek Canyon and oppose Alternative 2.1.6 which will infiltrate a ground/storm water blend of polluted water that will degrade the quality and quantity the water of Puget Sound Springs which discharge onto critical and sensitive near shore habitat that is vital to salmon recovery.

The interests of the citizens of the City of DuPont have been poorly represented during the entire MOU/FS process. Citizens have been relegated the role of spectators with their opportunity to participate limited to 15 minutes at the conclusion of FS meetings. Yet it is the citizens of DuPont whose property values, quality of life and surface water management fees are going to be most impacted by the decisions that are made by CalPortland, Environmental Coalition and governmental agency representatives. Unfortunately the City Manager, City Attorney and members of City staff have not acted in the best interests of the citizens of DuPont otherwise they would have applied and enforced the City's critical and sensitive area ordinances at the time that CalPortland applied for a Conditional Use Permit that allowed dewatering of the Vashon aquifer.

In the final analysis all the Alternatives that have been proposed and considered by the participants in the MOU/FS process that allow dewatering of the Vashon aquifer are fatally flawed if the purpose of the process is: *…to identify and evaluate alternatives for improving or restoring ecosystem functions in the Sequalitchew Creek watershed."*

**Subject:** City of DuPont FEIS Hearing Examiners Meeting commentary
**Attachments:** CALPORTLAND'S SEQUALITCHEW CREEK RESTORATION PLAN.docx; CALPORTLAND DEWATERING PROPOSAL.docx

Barb,

Yesterday morning I sat through a mind numbing presentation of the City of DuPont's FEIS response to Pioneer Aggregates South Parcel gravel mining proposal.

What is being proposed, if permitted, will result in **a missed opportunity disaster** for the private and governmental property owners of the City of DuPont since there is **no mitigation for the permanent ecological and financial damage that will occur as a result of dewatering the Vashon aquifer.**

The reason for my assertion is stated in the two attachments to this email.

At the time of my involvement (8 years) in assessing the impact of permitting dewatering of the Vashon aquifer I was the Technical Director of the Chambers-Clover Creek Watershed Council with years of experience in assessing the adequacy of the in stream flow and quality of a stream as suitable habitat for salmon.

It was apparent to me during my reconnaissance that the only Vashon aquifer dewater scheme that would result in a **win-win for CalPortland, the City of DuPont and salmon** was to require CalPortland to construct a Vashon aquifer groundwater discharge interception channel all along the southeastern shoreline of Edmond Marsh. This would result in a significant lowering of the groundwater level beneath the South Parcel and allow dry mining of gravel throughout the mineral overlay area 10 feet above the lowered Vashon aquifer groundwater level as per the 1996 Settlement Agreement.

The Hearing Examiner should find that what CalPortland/Pioneer Aggregates has proposed for mining the South Parcel is **not feasible** and CalPortland and the City of DuPont should convene a collaborative win-win process instead of its heavy handed "we are going to litigate if DuPont fails to give us the condition use permit that we have been seeking for decades now".

Environmental justice should prevail, not a "My way or the Highway" the dictatorial approach that I cite in my attachments.

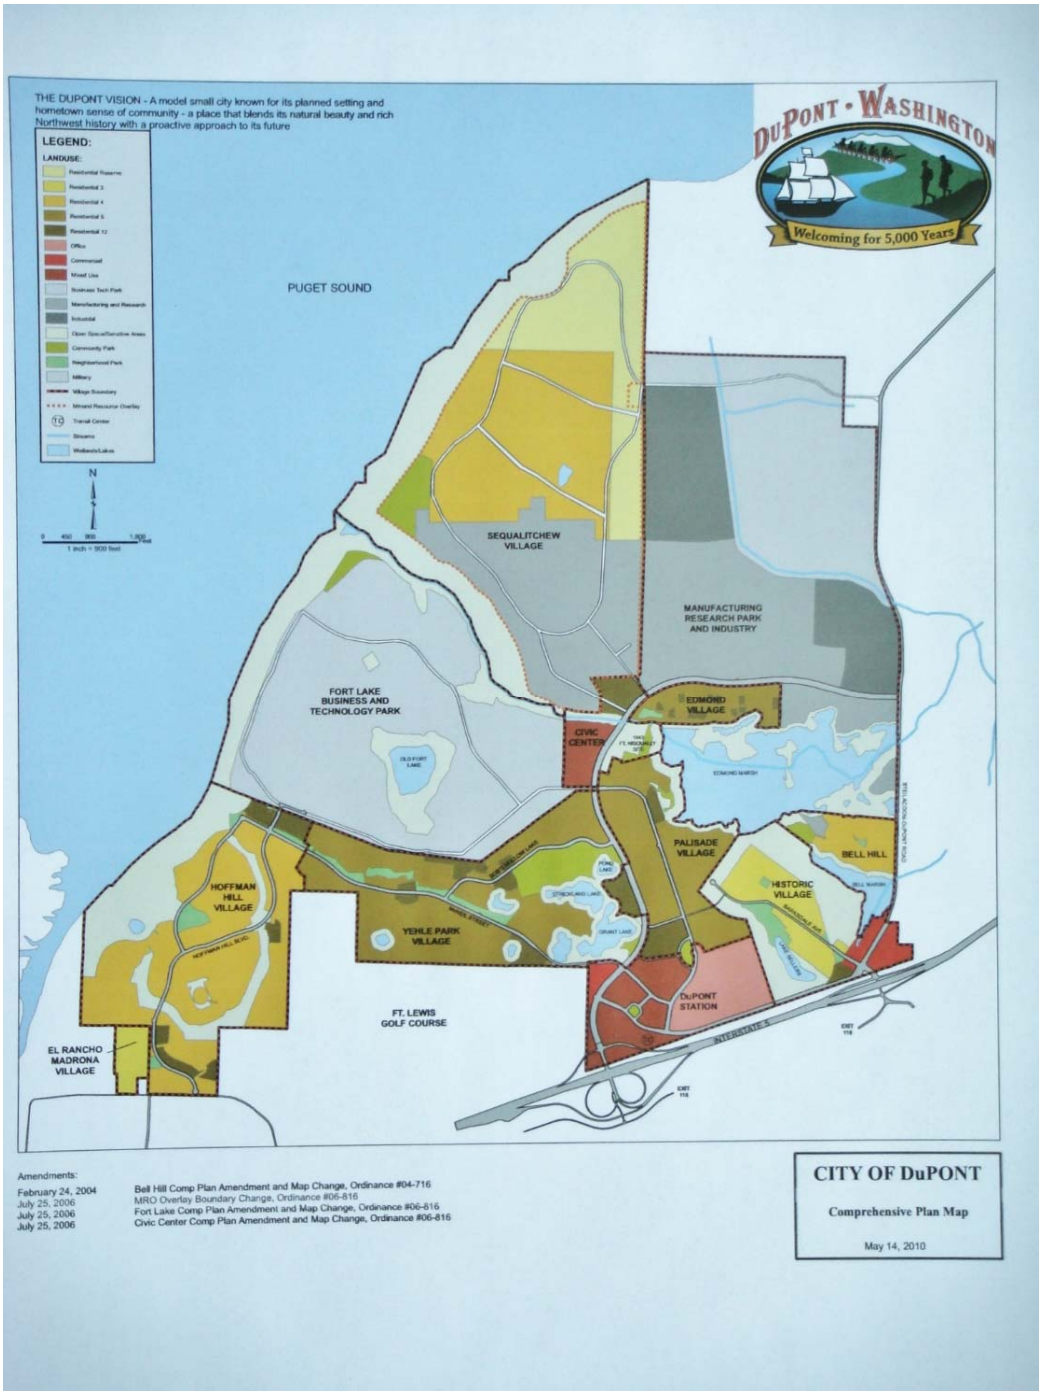
Don Russell

# CALPORTLAND'S SEQUALITCHEW CREEK RESTORATION PLAN

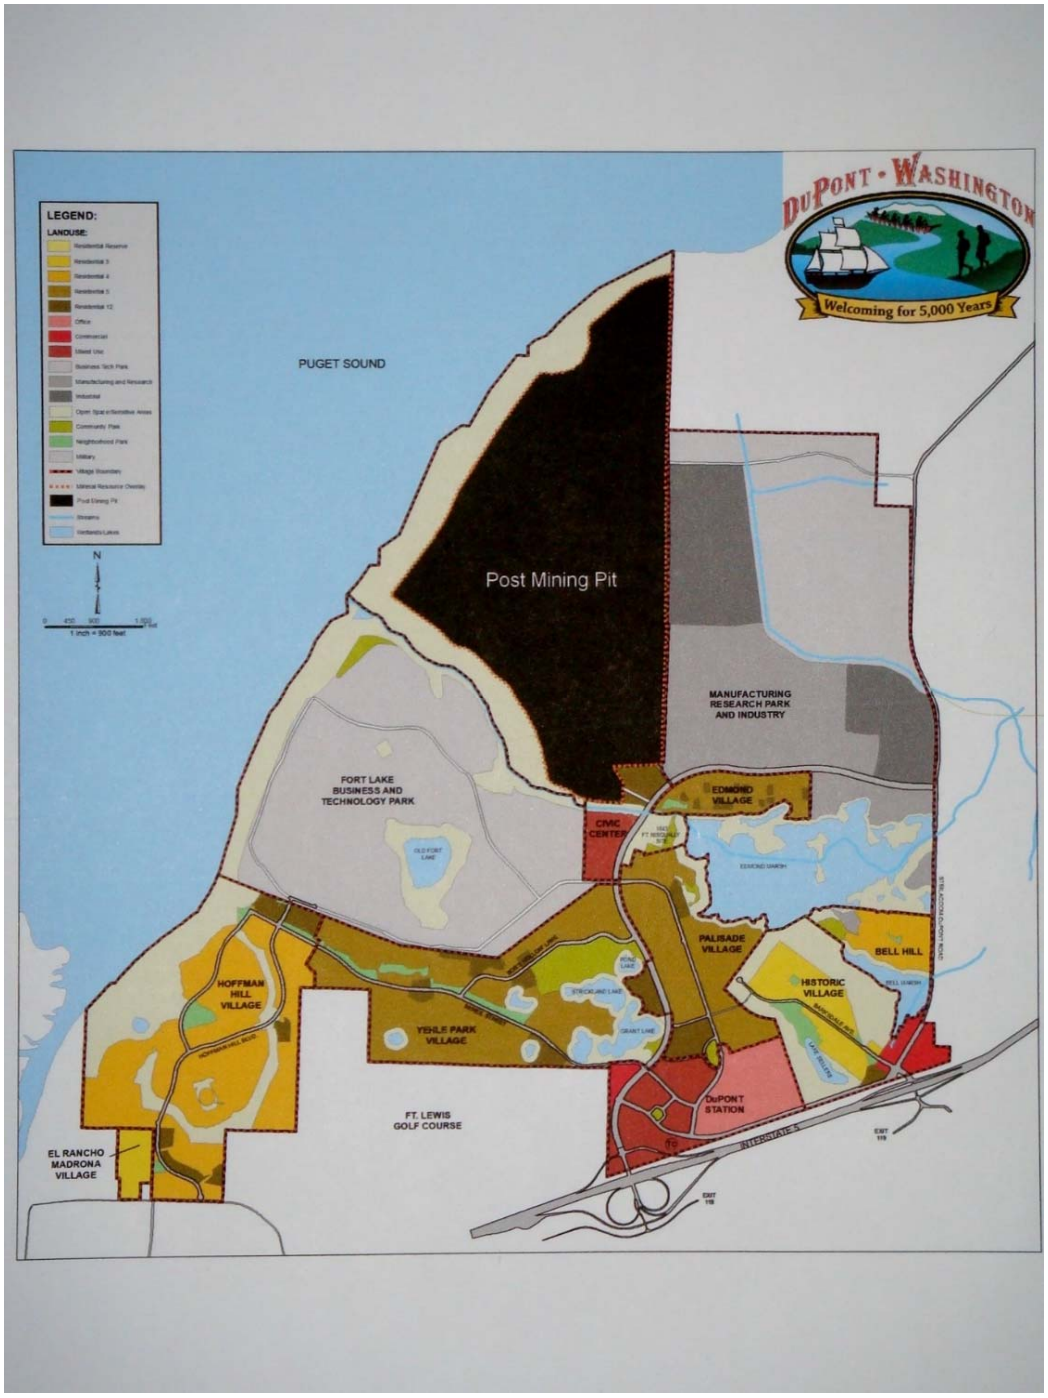
## Preface

This paper describes how Weyerhaeuser and CalPortland (under its several alias) have succeeded in manipulating events, data and people into accepting their version of the future of a once forested 700 acres of prime DuPont real estate.

## Weyerhaeuser's Vision as presented to DuPont's private property owners



**Weyerhaeuser/CalPortland's Vision of 700 acres of prime DuPont real estate**



**CalPortland's proposal for reconciling these two contrasting and contradictory visions**

In exchange for the City of DuPont issuing a conditional use permit to mine approximately 300 acres of Vashon aquifer groundwater saturated gavel contained within the footprint of its 700 acre gravel pit CalPortland has offered the City of DuPont a Sequalitchew Creek Restoration Plan that upon its implementation will render the site unfit for its intended future development.

**Origin of the Sequalitchew Creek Restoration Plan**

The CalPortland/Environmental Caucus/South Puget Sound Salmon Enhancement Group drafted Sequalitchew Creek Restoration Plan is the result of three decades of CalPortland's manipulation of events, data and people as chronicled below.

**1993 DuPont Quality-of-Life Committee Newsletter**

In June, 1993 a Neighbor to Neighbor citizen newsletter "*…dedicated to the great proposition that DuPonters have the right (and responsibility) to protect our quality-of-life and this region's historical and environmental integrity*" published an article in opposition to a proposed Weyerhaeuser/Lone Star DuPont 700 acre gravel mine.

The article is insightful since it described in detail Lone Star's (CalPortland) strategy for overcoming citizen opposition to its acquisition of a conditional use permit to mine gravel in land that it either leased or purchased in the City of DuPont under conditions that it dictated.

CalPortland's 1993 strategy was to provide DuPont's Planning Manager the necessary funding and consultants to draft a request that the City issue a conditional use permit to mine dry gravel in City designated mineral resource overlay areas and to convince the Mayor and City Council that approval of such a conditional use permit would benefit the City of DuPont. Should issuance of a conditional use permit to mine gravel be legally challenged by any outside party, i.e., citizens of DuPont or environmental advocacy group CalPortland would pay all the City's legal expenses necessary to defend the City Council's approval of issuance of a conditional use permit.

Application of this CalPortland strategy is manifest in all CalPortland manipulated events that have taken place since 1993. This strategy has been instrumental in determined the outcome of subsequent actions related to the development of the CalPortland/Environmental Caucus/South Puget Sound Salmon Enhancement Group drafted Sequalitchew Creek Restoration Plan. The Sequalitchew Creek Restoration Plan contains no relevant citizen stakeholder input.

Provisions of RCW 90.82 Watershed Planning assure that "*DuPonters have the right (and responsibility) to protect* [their] *quality-of-life and this region's historical and environmental integrity*" as codified below.

"*The purpose of this chapter is to develop a more thorough and cooperative method of determining what the current water resource situation is in each water resource inventory area of the state and to provide local citizens with the maximum possible input concerning their goals and objectives for water resource management and development.*" RCW 90.82.005

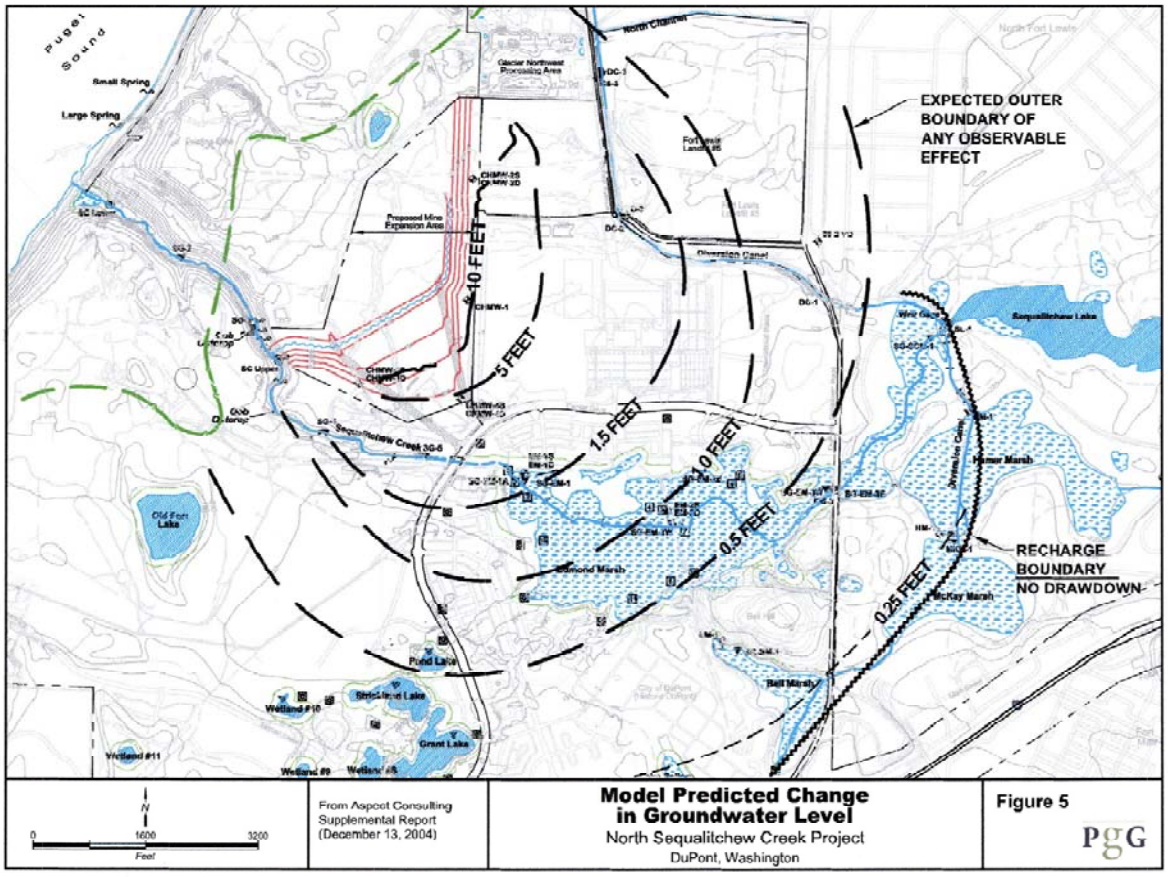
"*The local development of these plans serves vital local interests by placing it in the hands of people: Who have the greatest knowledge of both the resources and the aspirations of those who live and work in the watershed; and who have the greatest stake in the proper, long-term management of the resources.*" RCW 90.82.010

DuPonters have been denied "*the right (and responsibility) to protect* [their] *quality-of-life and* [DuPont's] *historical and environmental integrity*" contrary to provisions of RCW 90.82.

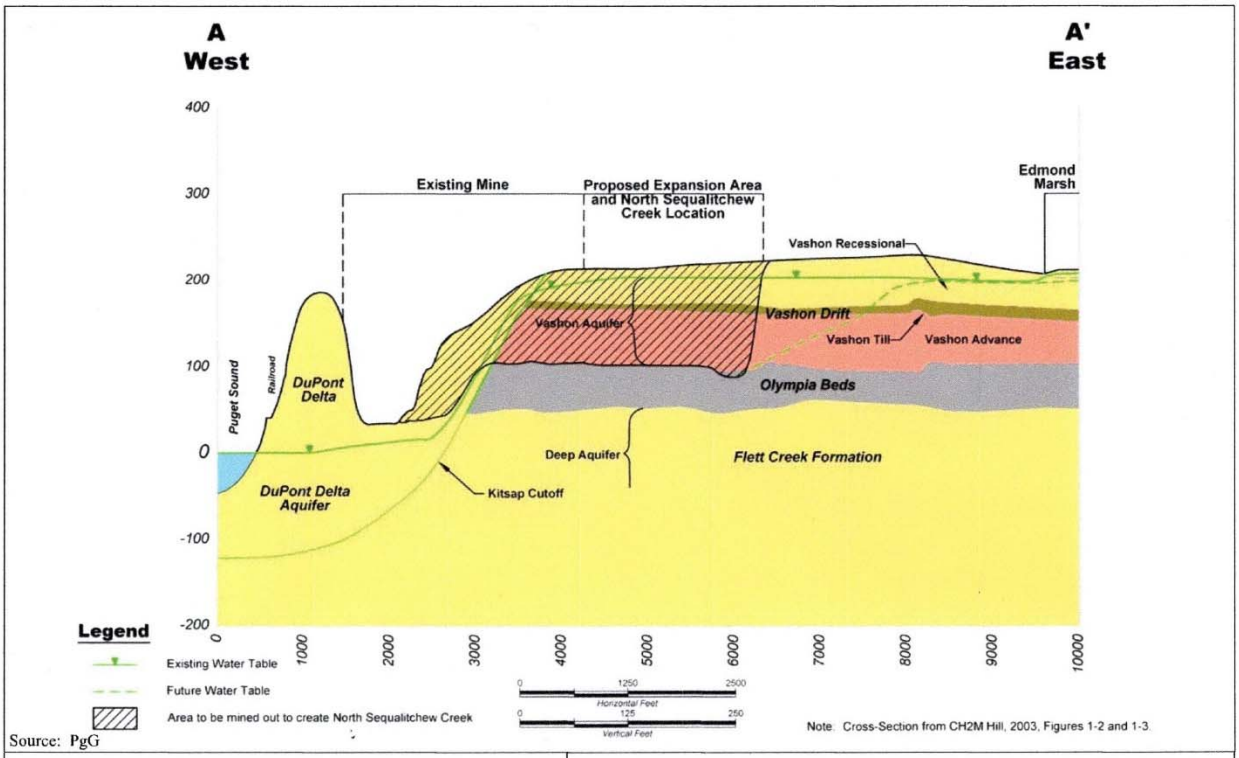
**The 1994 Settlement Agreement**

In 1994 in exchange for limited access and use of Weyerhaeuser owned land the City and several environmental advocacy groups (Environmental Caucus) entered into an Agreement that granted Lone Star (CalPortland) a conditional use permit to mine gravel in a 360 acre designated mineral resource overlay area. A key provision of that Agreement was "*WRECO and Lone Star agree to seek no permit in the future to mine…in a manner that would significantly impact the flow of Sequalitchew Creek.*"

During 2002-2006 Glacier Northwest (CalPortland) employed several consulting firms to study the hydrogeology of its existing 360-acre gravel mine and a proposed 170 acre south expansion area of its mine. The task was to come up with a plan (North Sequalitchew Creek) to access the Vashon aquifer saturated gravel that existed in 117 acres of its existing mine and in 170 acres of a leased south mine expansion area. These two areas were jointly referred to as the South Parcel.



The results of CalPortland consultants' studies are shown in the above illustration, i.e., a ground and surface water drainage ditch constructed at the base of the southeastern wall of the south mine expansion area. This in mine drainage ditch was intended to discharge its comingled groundwater and stormwater runoff through a cut in the southwestern mine wall and into lower Sequalitchew Creek. This proposal was called the North Sequalitchew Creek project.



This figure is from the Final Supplemental Environmental Impact Statement, Glacier Northwest DuPont Mining Area Expansion and North Sequalitchew Creek Project, May 1, 2007, Figure 3.4-1

**Figure 9**
**Generalized Geologic Cross Section**

553-3044-001/03(04) 1/09 (B) ai

The above illustration shows the location of the proposed in mine breached Vashon aquifer groundwater and stormwater runoff interceptor drainage ditch (aka North Sequalitchew Creek) perched upon impervious post mining exposed Olympia Bed material (center of the illustration). Note also that the post mining condition exposes impervious Olympia Bed material westward to a 25 foot drop off into the pervious bottom of the existing CalPortland DuPont mine.

**Expansion of DuPont's mineral resource overlay area**

In 2006 CalPortland persuaded the DuPont City Council to designate the entire 700 area shown in black on the second iteration of DuPont's Comprehensive Plan Map as a mineral resource overlay area. It included the South Parcel and a CalPortland owned North Parcel.

**2006-2008 The City of DuPont modifies its Comprehensive Plan**

The modification was done to reflect the expanded mineral resource overlay area and facilitate the permitting of Glacier Northwest's mining of both the South and North Parcels.

**2008 Nisqually Delta Association Intervention**

On July 16, 2008 the Nisqually Delta Association asserted that the proposed expansion of Lone Star's (CalPortland) gravel mine violated section II.B.5 of the 1994 Settlement Agreement's

provision "…*not to seek any permits to mine within the shoreline jurisdiction, within 100 feet of the top of the bank of Sequalitchew Creek, or in a manner that would significantly impact the flow of Sequalitchew Creek.*"

On January 4, 2009, the Nisqually Delta Association sent a Notice of Breach of the 1994 Settlement Agreement and Request for Mediation to Glacier Northwest and the City of DuPont.

**February 13, 2009 Don Russell submittal to DuPont's Hearing Examiner**

In my submittal I expressed opposition to the City's issuing a conditional use permit to Glacier Northwest for mining the South Parcel as proposed by Glacier Northwest's consultants and as conditioned by DuPont's Planning Manager on several bases.

Glacier Northwest's proposal envisioned the creation of an in mine 4000 foot long drainage ditch (aka North Sequalitchew Creek) to intercept 6.5 million gallons per day of breached Vashon aquifer groundwater discharging from the face of the steep eastern bank of the expanded South Parcel gravel mine plus any stormwater runoff from 287 acres of exposed South Parcel Olympia Bed impervious surface. This comingled discharging groundwater and polluted surface water runoff would then be conveyed through 500 feet of pipeline bored through the south wall of the mine and discharge into the Sequalitchew Creek ravine. Above this point of discharge there would be no groundwater discharge supplied base flow in Sequalitchew Creek.

I noted that execution of the proposed North Sequalitchew Creek plan would result in the elimination of Kettle Wetland and Sequalitchew Creek canyon Seep and Riparian Forest wetlands in violation of several of DuPont's sensitive areas regulations and RCW 78.44 that states *"…reclamation of mined lands is necessary to prevent or mitigate conditions that would be detrimental to the environment and to protect the general welfare, health, safety, and property rights of the citizens of the state.*" The post mining condition of a dewatered DuPont gravel mine would be in violation of provisions of this RCW mandate.

Subsequently a decision was made by the parties signatory to the 1994 Settlement Agreement to abandon the Hearing Examiner approach to resolving the dispute between the Nisqually Delta Association, Glacier Northwest (CalPortland) and the City of DuPont in favor of what became known as the Memorandum of Understanding/Feasibility Study process.

**Memorandum of Understanding/Feasibility Study process**

In 2010 CalPortland proposed that the concerned parties enter into a Memorandum of Understanding Agreement. This CalPortland drafted MOU Agreement contained the following provisions: (1) *This MOU reflects the parties understanding of the process that will be followed in an effort to <u>avoid protracted litigation</u> concerning the 1994 Settlement Agreement.* (2) *The purpose of the Feasibility Study will be to identify and evaluate potential alternatives for improving ecosystem functions in the Sequalitchew Creek's watershed. The <u>parties expressly recognize that mine dewatering</u> is one such an alternative*, and (3) *The parties will meet to develop a list of possible actions that would <u>mitigate the potential impacts</u> of the proposed project by improving, enhancing, or protecting ecosystem functions in the Sequalitchew Creek watershed*.

On February 2, 2010 I advised DuPont City Council to not enter into such an MOU/Feasibility Study Agreement on the basis that the CalPortland proposed North Sequalitchew Creek South Parcel mining proposal, if executed, would violate several DuPont sensitive area regulations and the post mining restoration provisions of RCW 78.44, as would any other dewatering proposal.

All of the identified and evaluated potential alternatives for improving ecosystem function in the Sequalitchew Creek watershed were fatally flawed. Nevertheless, one alternative was chosen as a result of the MOU/FS process. It was alternative 1.6 titled: Infiltrate a Portion of Dewatering and Post-mining Groundwater Discharge to Recharge Puget Sound Springs.

Derek Booth of Stillwater Sciences, consultant for the Environmental Caucus, described alternatives that proposed infiltration of dewatering water within the mine as: "*We find no basis to expect they will offer any net environmental gain and do not support their advancement.*"

I submitted a paper titled The Consequence of Dewatering the Vashon Aquifer to all parties to the MOU/FS Agreement that stated that the 1.6 alternative was more seriously flawed than was the original CalPortland proposed North Sequalitchew Creek dewatering proposal.

In September 2010 Ron Frederick requested that Mayor Jenkins form a citizen advisory group to advise the Mayor and City Council regarding growing citizen concern about CalPortland's undue influence on DuPont's Planning Manager and Hearing Examiner, the lack of application and enforcement of existing City of DuPont's sensitive area regulations, and the very limited opportunity afforded citizens to participate in the ongoing CalPortland/Environmental Caucus/City watershed planning process.

**2011 Settlement Agreement**

On June 24, 2011 Sally Toteff (DOE), Pete Stoltz (CalPortland) and Tom Skjervold (Nisqually Delta Association) announced "**Agreement reached on plan to help restore Sequalitchew Creek, allow new mining proposal."** This Agreement essentially removed most of the constraints to CalPortland's obtaining a permit to mine dry (North Parcel) and Vashon aquifer groundwater saturated gravel (South Parcel) from CalPortland's expanded (from 360 acres under provision of the 1994 Settlement Agreement to 700 acres under provisions of the 2011 Settlement Agreement) DuPont gravel mine.

I advised DuPont Council members in numerous papers (one of which was titled: Grounds for Not Approving the Settlement Agreement) and via public testimony that the City should not become a signatory to the 2011 Settlement Agreement for a variety of reasons. All of which would significantly reduce the City's ability to bargain with CalPortland for significant benefits that would accrue to DuPont's residents, private property owners, visitors, and tourists.

On January 26, 2012, the City of DuPont Council authorized Mayor Grayum to sign on behalf of the City of DuPont the CalPortland lawyer drafted 2011 Settlement Agreement.

**Sequalitchew Creek Restoration Plan**

The 2011 Settlement Agreement required that the Sequalitchew Creek Restoration Plan incorporate the below five elements (as defined by CalPortland's consultants Aspect and Anchor) in order for the Plan to be approved by CalPortland and the Environmental Caucus.

*4.1.1. Improvement of gradients so* [surface] *water discharges from Hamer and Bell Marshes flow into Edmond Marsh rather than into the diversion canal.*

*4.1.2. Improvements to create significant* [surface water] *flows from Sequalitchew Lake into the Edmond Marsh complex to support a functional creek ecosystem, and provide for the passage of migratory fish in the Sequalitchew Creek system. To achieve this goal, the Parties will consider, at minimum, modification of the diversion canal flood control structure and gradients.*

*4.1.3. Rehabilitation of Edmond Marsh by removal of sufficient fill and other flow impediments to provide the hydraulic gradients and capacity necessary to achieve and maintain adequate* [surface water] *flows through the Marsh.*

*4.1.4. Rehabilitation of Sequalitchew Creek below Edmond Marsh to reduce seepage, improve fish habitat, and help restore year-round* [surface water] *flows.*

*4.1.5. Active management of beaver activities to maintain the hydraulic gradients that provide* [surface water] *flows through Hamer, Bell, and Edmond marshes. For purposes of this section, "active management of beaver activities" means management commencing with the least intrusive method and progressing to more intrusive methods only as necessary to maintain hydraulic gradients and flows, with lethal removal utilized only as a last resort.*

The above inserted bracketed words make it clear that CalPortland incorrectly assumed that Sequalitchew Creek is a surface water driven system. It is not. It is a groundwater discharge driven system. Herein lies the fallacious foundation of the CalPortland consultant drafted Sequalitchew Creek Restoration Plan.

Unfortunately, these CalPortland consultant prescribed elements were never vetted by others to determine whether or not they were grounded in a proper characterization of the 2011 condition of the Sequalitchew Creek watershed. What existed then (on the left) and what exists now (on the right) is best illustrated by a comparison of the two below photographs. In stream flows are dependent upon shallow aquifer groundwater levels. Ground water withdrawals (dewatering) are antithetical to surface water flow in the Edmond Marsh/Sequalitchew Creek ecosystem.

CalPortland's consultants characterized the Sequalitchew Creek/Edmond Marsh complex as a surface water driven system. It is not. It was a groundwater driven system that over the years has been adversely impacted by ever declining Vahon aquifer groundwater levels and ever increasing quantities of stormwater runoff being discharged into this once pristine salmon bearing groundwater fed stream and associated wetland complex.

What CalPortland's consultants monitored during the period from 2003 up until till 2011 and upon which the Sequalitchew Creek Restoration Plan was built no longer represents the condition of the Sequalitchew Creek watershed today. The Sequalitchew Creek Restoration Plan proposed by CalPortland's consultants is not relevant to addressing today's degraded condition of Edmond Marsh and what little is left of a naturally flowing and functioning Sequalitchew Creek.

**A Relevant Sequalitchew Creek Restoration Plan**

A relevant Sequalitchew Restoration Plan would recognize that a further and permanent lowering of the Vashon aquifer groundwater level beneath the Edmond Marsh/Sequalitchew Creek complex as proposed by CalPortland's dewatering proposal is antithetical to restroration of a groundwater discharge fed salmon bearing Sequalitchew Creek flowing through an associated groundwater sustained Edmond Marsh wetland.

The elements of such a plan would be the control of the surface water levels of upgradient groundwater fed, occasionally stormwater runoff polluted, Bell, McKay and Hamer Marshes so as to provide the necessary hydraulic head to cause water contained in these marshes to infiltration into the underlying groundwater that flows subsurface (not on the surface) to discharge into lower elevation level Edmond Marsh.

To facilitate the interception of this subsurface flow of groundwater and enhance the volume of its discharge into Edmond Marsh a Sequaltichew Creek channel should be constructed (dug) all along the eastern boundary of Edmond Marsh by CalPortland. This is the proper location for constructing a discharging Vashon aquifer groundwater intercepor channel, not at the bottom of a breached Vashon aquifer groundwater discharge/stormwater runoff flooded gravel mne pit!

**Action Required**

The Mayor and City Council should start acting on behalf of the citizens of the City of DuPont that they represent instead of acceding to CalPortland's under threat of "*protracted litigation*" demands.

The proposed Sequalitchew Creek Restoration Plan offered by CalPortland is a bright and shiny bauble to attract attention away from the fact that its execution will cause permanent and irreversible environmental harm to a groundwater disconnected Edmond Marsh/Sequalitchew Creek complex and a lost opportunity for what could become a salmon bearing Sequalitchew Creek flowing through the center of the City of DuPont.

If the proposed CalPortland Sequalitchew Restoration Plan is executed not only will Edmond Marsh/Sequalitchew Creek be lost forever, DuPont private property owners will be paying to operate and maintain an in mine facility to handle 6.5 million gallons per day of discharging groundwater comingled with a like quantity of polluted stormwater runoff in an area designated by the City to become Sequalitchew Village residential and industrial area real estate.

**Conclusion**

I have written and circulated numerous papers on the proper characterization of the Edmond Marsh/Sequaltichew Creek complex, how Mother Nature intended this complex to work, how the actions of humans have impaired its natural function, almost beyond the ability to restore it, and, importantanly, how at this late date this complex can be restored as desirable salmon habitat, an aesthetic ammenity to be enjoyed by the citizens of DuPont, and a popular tourist destination.

July 6, 2011 paper titled Commentary on the Settlement Agreement sent to Mayor and Council members with an attachment titled CalPortland's Promises vs Its Performance noting that CalPortland has a poor track record of fulfilling its promises as evidenced by its violation of provisions of the 1994 Settlement Agreement and DNR provisions of its mining permit.

July 8, 2011 paper titled The Untold Story Behind the Settlement Agreement

July 9, 2011 DJR refutes Ecology's claim that there will be no adverse impact on the City of DuPont's domestic water supply as a result of permitting CalPortland to dewater the Vashon aquifer.

Sometime in July 2011 the October 1, 2010 Mayor appointed Sequalitchew Creek/Edmond Marsh Committee issues its Final Report. It contained 10 Recommendations on how the City of DuPont and its citizens can work together to provide protection of its valuable natural resources.

August 2, 2011 paper titled Grounds for Not Approving the Settlement Commentary on Settlement Agreement submitted to the Mayor and City Council members.

September 2, 2011 DJR Letter to Sally Toteff (Ecology) with copies to City Council members complaining about the brief amount of time allowed five citizens to speak of their opposition to the City Council authorizing the City of DuPont Mayor to become a signatory to the 2011 Settlement Agreement.

September ?, 2011 Gendler and Mann (attorneys) letter to Mayor Jenkins and City Council stating: *"You may believe that the Settlement Agreement does not bind you to any specific course of action and that you may therefore approve it prior to your review of the SEPA analysis. This belief is wrong for at least two significant reasons. First and foremost, ask yourselves the simple questions - if the Settlement Agreement does not bind the City to any course of action, then why are you signing it? Why does CalPortland want you to sign it? The answer should be obvious -by committing itself to the Settlement, the City is giving at least the appearance of cooperation and that it will issue the future permits. Indeed, the Settlement Agreement confirms in Section 12 that "based on existing information and analysis the Governmental parties believe they can issue permits consistent with this agreement." But the City is not in "believe" that permits may be issued for this project - especially at this early date. The City owes to itself and its citizens the responsibility and duty to remain absolutely and completely neutral.*" The letter went on to state: "*The City should decline to participate in the Settlement. The City should instead follow the process set out by SEPA and its implementing regulations, and, prior to making any decisions on CalPortland's proposal, fully educate itself on the complete environmental ramifications of your decisions.*"

September 6, 2011 DJR Power Point presentation titled Hydrology and Geology of DuPont.

September 27, 2011 DJR addresses the Mayor and City Council expressing opposition to the City signing the 2011 Settlement Agreement since it would commit the City staff to support CalPortland's quest to dewater and mine the South Parcel. That address is documented in a paper titled Public Hearing Comments on the 2011 Settlement Agreement.

September 30, 2011 DJR Power Point presentation titled Commentary on Settlement Agreement

October 2, 2011 Diana Barbera Letter published in The Suburban Times bearing the title DuPont Resident opposes [2011 Settlement] agreement.

January 26, 2012 paper titled Final Comments on the 2011 Settlement Agreement citing reasons why the City Council should not authorize the Mayor to become a signatory to the 2011 Settlement. It concluded by stating: "*…the role of the DuPont City Council should be to preserve, protect, restore and enhance the wellbeing, property values and quality of life for the citizens of DuPont by not approving the 2011 Settlement Agreement which promotes the commercial interests of CalPortland whose expanded South Parcel mining activities would diminish the value of all that the citizens of DuPont cherish about their City.*"

On January 26, 2012, the City Council voted in favor of authorizing the Mayor to sign the 2011 Settlement Agreement that pledged the City to support CalPortland's 1994 to 2011 quest to obtain a permit to dewater and mine the South Parcel.

January 29, 2012 DJR submits a Letter to the Editor of The Suburban Times under the banner The Consequence of the City of DuPont Council Approving the 2011 Settlement Agreement. That article concluded with the statement: "*There is no mitigation that will offset the adverse impacts that lowering the groundwater level in DuPont to facilitate mining saturated gravel in 117 acres of CalPortland's existing mine and in 180 acres of a leased south expansion area collectively known as the South Parcel will have on the natural function of Edmond Marsh, Sequalitchew Creek, Kettle Lake (to be eliminated), Sequalitchew Creek Ravine Riparian Forest and Springs and Puget Sound Shoreline Springs all of which are dependent upon their connectivity to and continuity with Vashon aquifer groundwater.*"

What followed in subsequent years was CalPortland's consultants (Anchor and Aspect), Nisqually Delta Association (Tom Skjervold) and South Puget Sound Salmon Enhancement Group (Lance Winecka) discussions on how to implement provisions of CalPortland lawyers' crafted 2011 Settlement Agreement. These discussions were closely held, resulting in precluding any DuPont citizen and concerned watershed stakeholder input. What emerged from these discussion was the CalPortland consultant crafted Sequalitchew Creek Restoration Plan.

In 2017 I provided the City of DuPont a proposed City managed Edmond Marsh/Sequalitchew Creek restoration plan. This plan was based upon a proper characterization of the condition of the Edmond Marsh and Sequalitchew Creek ecosystem. It was titled Edmond Marsh Fact vs [CalPortland's] Fiction.

Bottom line: CalPortland's proposed Vashon aquifer dewatering interception channel should be constructed by CalPortland paralleling the eastern shoreline of Edmond Marsh and be named coho salmon friendly groundwater fed Sequalitchew Creek and its off channel associated Edmond Marsh wetlands. It should not be located at the bottom of a mined out gravel pit that is subsequently slated to be developed as Sequalitchew Village (featuring Kettle Lake) and light industrial park that does not experience, in perpetuity, continuous groundwater discharge exacerbated by intermittent stormwater runoff flooding events.

Don Russell

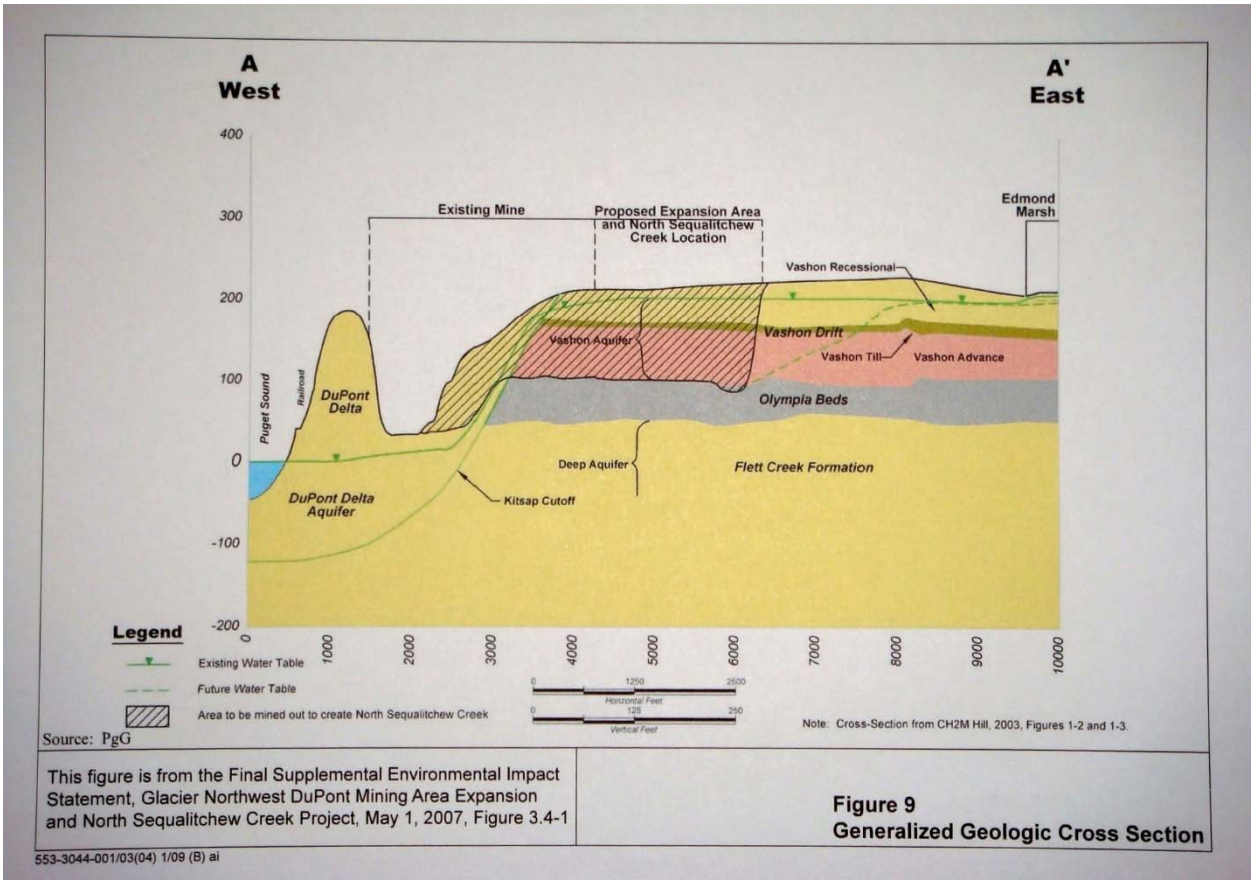
## THE EFFECT OF DEWATERING THE VASHON AQUIFER

### Preface

This paper is in response to Al Schmauder's question about the effect of CalPortland dewatering the Vashon aquifer to access groundwater saturated gravel in 117 acres of its present mine plus 177 acres in a south expansion area of its gravel mine. His question was: *If groundwater is withdrawn from the Vashon aquifer SE of Edmunds Marsh, wouldn't it dry up the marsh?*

The short answer to that question is Yes. A more detailed answer to the question is provided below.

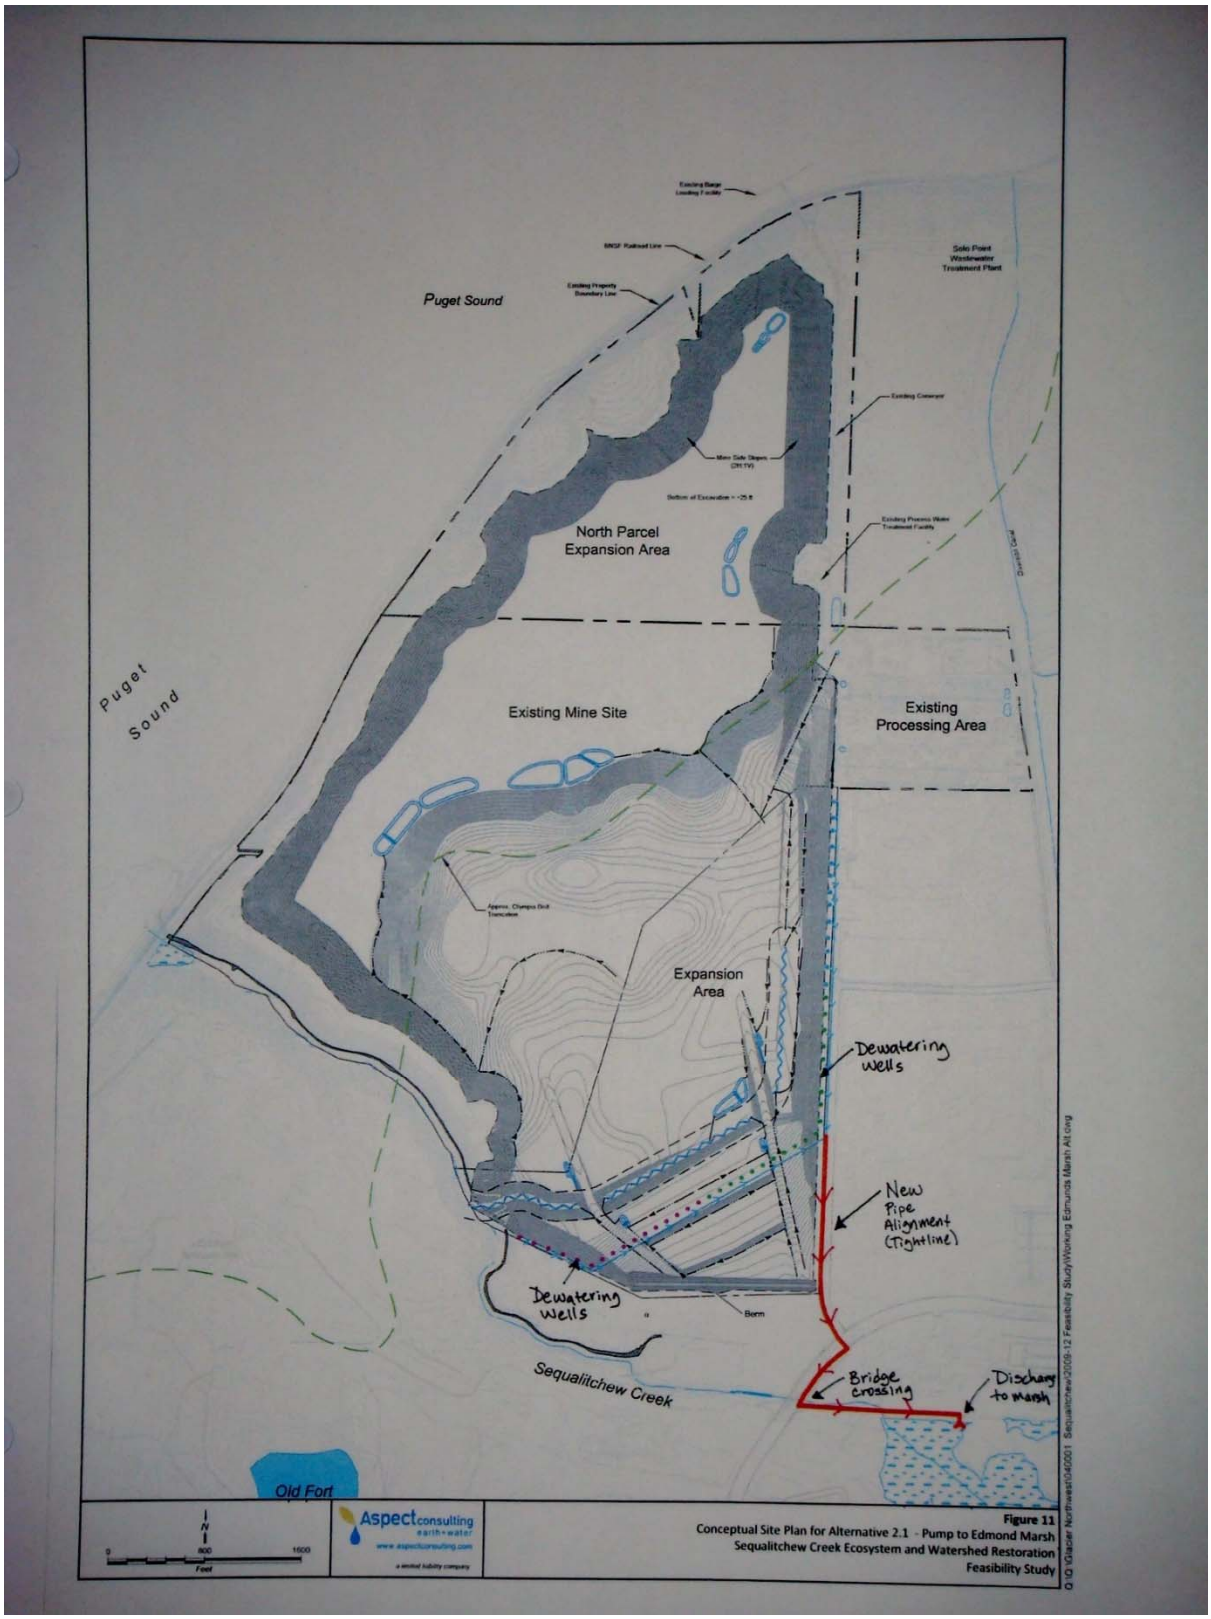
### Pre and post Vashon aquifer groundwater level before, during and after dewatering



This is the cross section of the hydrogeology of the area. The green line with inverted pyramids shows the existing Vashon aquifer groundwater level. The green dotted line shows the Vashon aquifer groundwater level during and after CalPortland's dewatering of the area.

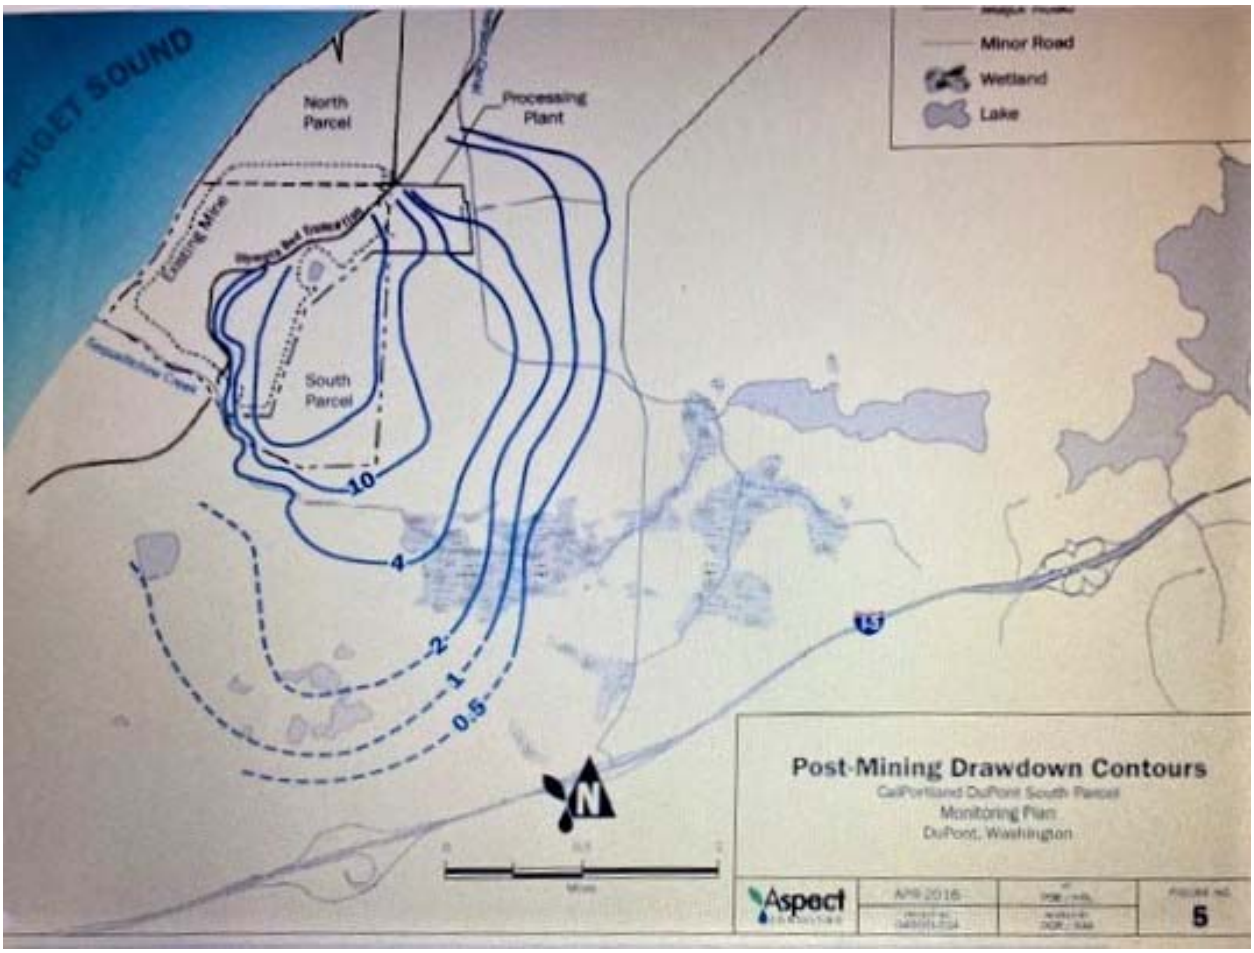
Note that the solid green line is shown as underlying and supporting groundwater that currently manifests itself as surface water in Edmond Marsh whereas after the dewatering pumps are turned off and removed that the Vashon aquifer groundwater level will be well below Edmond Marsh. Disconnect the groundwater that supports Edmond Marsh and it will dry up.

How CalPortland proposes to dewater the Vashon aquifer is show in the below illustration.



Note the extensive array of dewatering pumps around the south and east perimeter of the mine pit. Also note that the combined discharge of these pumps is discharged into Edmond Marsh.

This technique will provide substantial pumped groundwater flow from the west end of Edmond marsh and down the ravine reach of Sequalitchew Creek. However, once the dewatering pumps are turned off and removed water in Edmond Marsh and flow in the ravine reach of Sequalitchew Creek will disappear. The effect of dewatering on groundwater level is illustrated below.

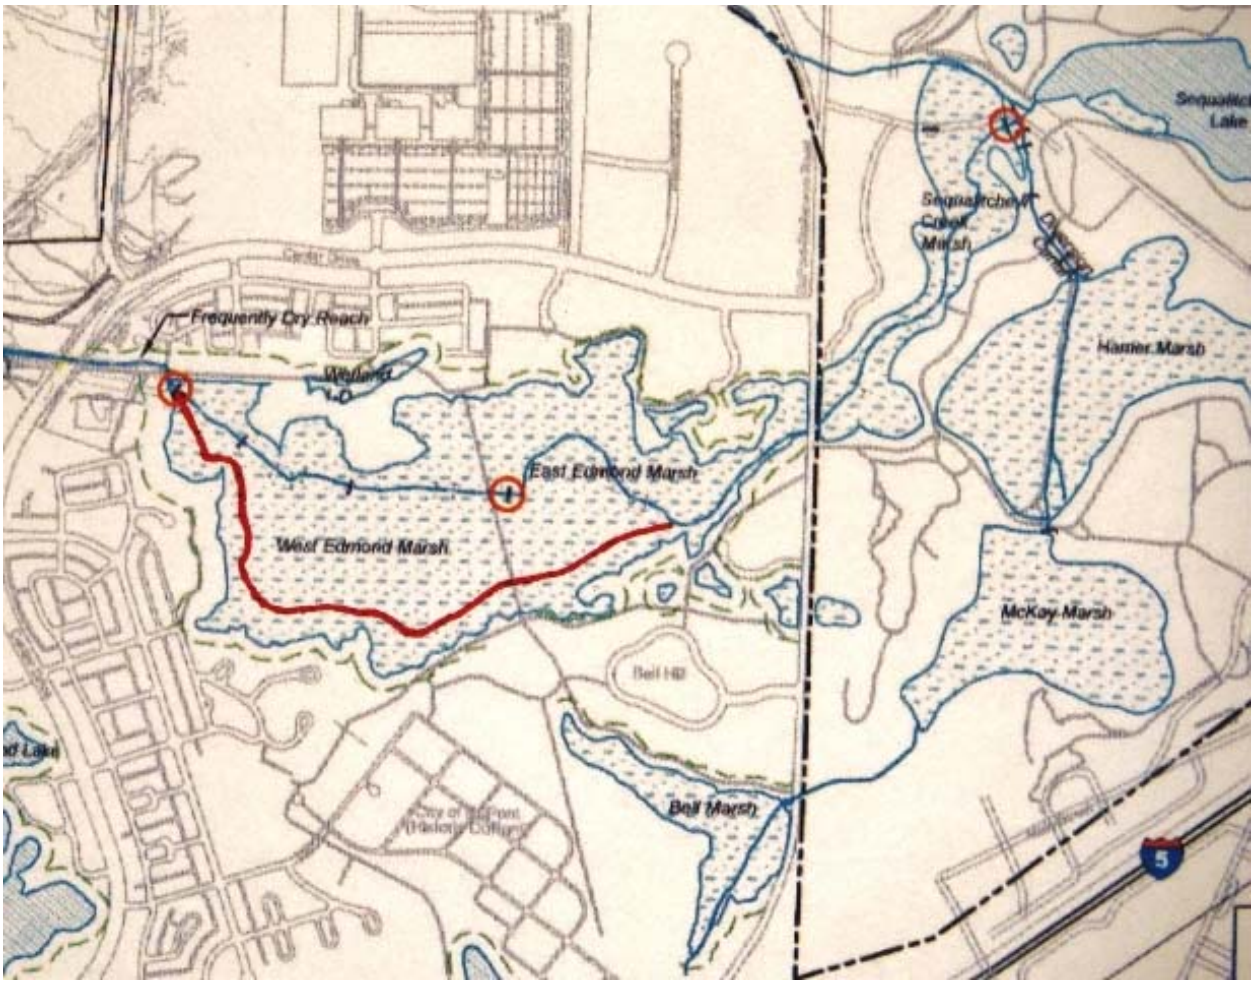


**Consequence of permitting dewatering of the Vashon aquifer**

It will only become evident when the dewatering pumps are turned off 14 years hence that the disastrous ecological effect will become evident to the Department of Ecology, Environmental Caucus members, Nisqually Tribe, WDFW, DNR and the citizens of DuPont.

There will be no viable salmon habitat in the Sequalitchew Creek sub watershed, no functional Edmond Marsh wetland, and no groundwater discharge flow in Sequalitchew Creek. In other words, the Sequalitchew Creek watershed will become as groundwater discharge deprived and dysfunctional as much of the Clover Creek subbasin watershed.

There is an environmentally friendly way of lowering the Vashon aquifer groundwater level beneath the South Parcel. That is, to intercept the southeast to northwest subsurface groundwater flow of the Vashon aquifer by constructing a groundwater interception and discharge fed Sequalitchew Creek all along the eastern boundary of Edmond Marsh as shown in red on the below illustration.



Such a constructed Vashon aquifer groundwater interception channel would assure perennial Coho salmon inhabitable groundwater discharge flow from east to west through Edmond Marsh and down the ravine reach of Sequalitchew Creek.

The notion that warm, low dissolved oxygen concentration surface water flow from Sequalitchew Lake and stormwater runoff polluted surface water flow from Bell, McKay and Hamer Marshes can restore a natural functioning Edmond Marsh wetland and upper flowing reach of Sequalitchew Creek is a fatally flawed.

Such a Plan as mitigation for the irreversible ecological damage that executing CalPortland's proposed dewatering of the Sequalitchew Creek sub basin watershed will have should be embraced by no one who is familiar with Coho salmon habitat requirements.

Barb,
I am a concerned citizen of this Cal Portland mine expansion in DuPont. Something is just not right when wording is changed by the City on the
environmental impact findings that are changed from "significant impacts" to "minor impacts" just hours before the CalPortland mining hearing.
All this sounds pretty shady. You did not disclose this to the public and in the document that was changed the night before or morning of hearing.
THIS is ILLEGAL under Washington State Environmental Policy.

This project will severely decimate Sequalitchew Creek and surrounding area.

I OPPOSE CALPORTLAND MINE EXPANSION.
Thank you.
Nancy Taylor

**Subject:** OPPOSE Pioneer Aggregates Mine Expansion - PLNG2021-006 - My Testimony

To: Hearing examiner and Dupont city staff,

Growth is unavoidable... However, the balance approach is always needed, within legal limits. That's why city has living and working documents called "Comprehensive Plan" & "critical area". It takes years of hard work of several individual volunteer citizens of city & staff hours to format, review and update time to time.

For the same reason on June 20th: presentation started with Comprehensive Plan.

Not following the agreement / document should not be an option and it is violation on law.

STAFF REPORT & RECOMMENDATION TO THE HEARING EXAMINER June 13th 2025 Page 11 & 12

Finds many inconsistencies for development plan vs comp plan requirements.

I Jugal Thakor as a DuPont resident find it's difficult to approve this project.

In the best interstate of city and its citizens, I oppose this project.

Thank you

Jugal Thakor

**Subject:** Additional Responses to the Pioneer Aggregates South Parcel Project following last Friday's meeting.

I have been living in DuPont for 5 years and hope to happily live here for the rest of my life. I love this area for its history, its community, and its abundant natural areas and local wildlife from amphibians, to deer, and birds. I am concerned that more than one of DuPont's main assets may possibly be destroyed. I am appalled at the behavior of the community development board in allowing the Pioneer Aggregates South Parcel Project to continue to proceed to this point, especially given the slipshod responses from CalPortland to very serious concerns. They mentioned in last Friday's (6/20/25) hearing that "they have listened to the community" while providing nothing more than lip service.

There has been no adequate response to the serious adverse effects of their de-watering plan. Draining the Vashon aquifer will permanently alter the landscape and destroy important habitat for all local wildlife. The Kettle wetland replacement would have to be simultaneous to the removal in order to preserve the life of the local amphibian population or they will simply die out with noplace to relocate. Pumping aquifer water back up to the creek to mitigate the reduction in water flow as a result of removing it in the first place is only a short-term solution that will stop as soon as the project has stopped. In addition to the devastation of local wildlife, many of which will simply die as a result, there has been no discussion of the effects on the DuPont Historic Orchard which abuts Edmond's Marsh. This orchard dates back to Fort Nisqually and contains heritage fruit varieties grown here during that time. These trees are very old and their future has not been secured. Reducing the water table could kill these sensitive trees.

CalPortland's assertion that the Sequalichew Creek restoration will mitigate the impact to the local wetlands by restoring (admittedly higher temperature) flows to the creek is predicated on them accomplishing the restoration at all. CalPortland has made no measurable progress with this restoration project that is still part of a previous agreement in nearly two decades. This restoration project is starting to feel like a stick dangled in front of an emaciated mule at this point. This is saying nothing of the fact that this project is carrying a lot of weight in this current proposal for something that shouldn't be considered as part of this proposal. Given that they have not accomplished the requirements laid out from the previous agreement, the discussion of this project is starting to feel like a bad faith negotiation.

This project is disastrous to wildlife and will permanently alter the landscape and the character of our community, not to mention further eroding trust in our local government to act in our best interest. Why is an outside company being given carte blanche to permanently destroy our home so that they can profit for an additional 14 years before leaving us with the bill. Put a stop to this NOW!

With Great Concern,

Kelly Unekis

📋 SUBJECT: OPPOSE Pioneer Aggregates Mine Expansion - PLNG2021-006

Dear Hearing Examiner,

I oppose the Pioneer Aggregates South Parcel Mine Expansion (PLNG2021-006).

City staff admits this project violates the Comprehensive Plan AND Critical Area Ordinance. The Staff Report states it "does not align with Comprehensive Plan policies" and admits "no mitigation is provided for the significant unavoidable impacts to the surface water bodies" - directly violating DMC 25.105.050, which REQUIRES mitigation "to achieve no net loss of stream function."

Scientists in the Final EIS admit "significant unavoidable adverse impacts" including:

• 83% creek flow loss along the Sequalitchew Creek trail from drying up natural seeps and springs

• Vashon Aquifer levels dropping 8+ feet permanently

• Multiple wetlands losing 1-3 feet of water forever

• Creek temperatures getting too hot for fish survival

• Seep wetlands along the creek ravine disrupted permanently

The EIS states the restoration plan "would likely NOT mitigate these impacts."

The Nisqually Indian Tribe never signed the 2011 Settlement Agreement that underlies this entire project. The sovereign tribal nation is formally appealing the Final EIS, citing:

• Failure to properly identify tribal cultural resources

• Violation of tribal consultation requirements

• No adequate mitigation for impacts to sacred sites

How can you approve a project without consent from the sovereign tribal nation on their ancestral lands?

The city's conditional approval requires 38 conditions to "mitigate" environmental damage that the reports already prove cannot be mitigated. You cannot require the impossible. Plus, CalPortland has had OVER 15 years to provide the mitigation requirements in the Critical Areas Ordinance.

How can you approve a project that:

• Violates city law (Comprehensive Plan AND Critical Area Ordinance)

• Requires fixing damage scientists say CANNOT be fixed?

• Demands impossible mitigation conditions?

This is legally impossible. DENY the approval.

Sincerely,

Dr. Sean Valdez

**Subject:** Comments on Hearing Examiner extension.

Dear Hearing Examiner and Ms. Kincaid,

I attended the recent hearing on the Pioneer Aggregate mining company's Environmental Impact Statement and signed up to speak, but I had to leave for work at 12:15 pm and could not wait to speak. I am submitting these comments in addition to the letter I submitted before the June 20 hearing, that you acknowledged receiving Ms. Kincaid, and that I assume the Hearing Examiner also possesses. My additional comments are:

The mining company's impact statement must meet DuPont's Critical Ordinance requirements, particularly that under its environmental impact plan there will be no net loss of wetland and stream function. But the mining company acknowledged, under oath, that it could not testify there would be no net loss of wetland and stream function under its plan. Thus, the plan cannot meet the critical ordinance requirement and should be rejected.

Witnesses including the mining company's Mr. Wright, testified that dewatering the Vashon Aquifer could permanently, significantly lower and negatively change groundwater levels, diminish water flow of the creek and the springs that feed the creek and the forest marshland, and increase the water temperature of the creek and adjacent streams, thus destroying salmon habitat. In testimony, the mining company acknowledged that the impact of dewatering the Vashon aquifer and wetlands may significantly change and negatively affect wetland functions. And the company's witness stated under oath that he could not say that the EIS would mitigate all the negative impacts of the mining company's activity. This is not a finding of "no net effect," it is an admission of net effect. It does not meet the critical ordinance requirement.

The mining company plan includes cutting down 188 mature fir and forest trees, which are the habitat and source of food for hundreds of birds, mammals, and fish, and whose shade cools springs and streams. The mining company testified that it would mitigate the environmental harm of cutting down the trees by planting seedlings. But this is not persuasive. Seedlings are 2 to 20 inches high, and take 20 to 80 years to mature to 30 to 300 feet, depending on the tree species. 2 to 20 inch seedlings are not comparable to the mature trees the mining company is going to destroy here and seedlings cannot serve the same functions as mature trees, cooling streams and sustaining wildlife. And the mining company does not say it will remain in DuPont to water and grow the seedlings for 20-30 years, when they mature. Nor does it say who will provide/pay for the water for the seedlings/juvenile trees at a time of water shortage and increasing heat (as described by Christina Mineti, testifying for herself and the environmental group).

Finally the mining company asserts it is not destroying the forest marshlands, it is just moving them. But it relies in part on the errata sheet first revealed at the end of the June 20 hearing, in which the city, without notice, changed its assessment of the effect of the mine expansion on off site wetlands from

"significant" and "unavoidable damage" to "minor" damage. The city said it could not further comment on the no net loss. This raises questions about the validity and credibility of the city's "minor" assessment. Moreover there are no details on how the mining company is going to recreate a decades-old unique forest marsh environment. And as with the seedling mitigation for the 188 cut down trees, who will pay for, water, and tend the affected  Edward and Kettle  forest marshland environment for the years required to create a new marshland. It seems like another disingenuous "mitigation" that never will/could happen.

Thank you for providing additional comment time for those who attended the hearing and signed up to speak, but had to leave before comments were taken. And Ms. Kincaid if  you would please confirm the timely receipt of this comment and give it to the hearing examiner.

Sincerely

Kate Walsh

Ms. Kincaid.

I sent a comment on the mine expansion on Monday, the 23rd, w/in the three day period the Examiner allowed.

Later that day I realized there was a typo - I mistakenly said Mrs. Martin ~~worked~~ for the mining company, not the city.

So yesterday, Monday, the 23d I sent you a typo correction ~~regarding~~ Mr. Martin, correcting that he testified works for the city. And I sent you that correction in email, in the same email chain as the comment. I want to confirm that you received AND WILL MAKE PART of THE RECORD my original comment (6/23) AND the correction regarding Mr. Martin (also 6/23). Nothing else in the comment has changed - just the correction. I especially do want to know that you

are making the June 23 comment correction & the June 23 ~~Correction~~ part of the record for the Hearing Examiner. I emailed 2x, & want to confirm that the comment & correction are accepted b/c the 3-day period expired. Thanks for letting me know that.

Hi Barb,

Just now, June 26, I called your listed work phone number and left a vm:

Did you get my June 23 comment re: the mining expansion? Did you get the single correction stating who employs Mr. Miller, submitted by email June 23rd and also submitted in writing and stamped received, at city hall on June 24? and have you included my comment with correction in the hearing record for the mining expansion matter, submitted w/in the time period the hearing examiner allowed?

Thanks for responding, Ms. Kincaid,

**To:** Barbara Kincaid
**Subject:** Opposition to CalPortland Gravel Mine expansion

Dear Ms. Kincaid:

As a member of Tahoma Bird Alliance, South Sound Bird Alliance and Mountaineers, I am writing to express my strong opposition to expansion of the Pioneer Aggregates CalPortland Gravel Mine in Dupont.

Draining the Vashon Aquifer to gain access to the gravel beneath it is a terrible idea. This proposed action risks drying out Sequalitchew Creek and endangering birds, salmon, and other wildlife that rely on the riparian forest habitat the creek supports. Riparian forests rely on steady sources of groundwater, so draining this aquifer will lead to drastic habitat changes and tree die-off along the beloved Sequalitchew Creek Trail. In addition to endangering the forest, draining the Vashon Aquifer may destabilize slopes, exacerbating preexisting erosion risks, and mining in the area will disturb sacred Nisqually tribal burial sites.

The cumulative impacts of this project—environmental degradation, cultural desecration, and community harm—are unacceptable. The proposed mitigation measures are inadequate and fail to address the
long-term consequences of the mine's expansion. I strongly urge you to protect our water, forests, wildlife, and the cultural and environmental integrity of this cherished region by rejecting the expansion of the CalPortland Gravel Mine.

Thank you!

Linda Whipple
University Place, WA

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Dear Hearing Examiner ,

As a deeply concerned citizen, I am writing to express my strong opposition to the proposed expansion of the Pioneer Aggregates South Parcel Project, as detailed in the Final Environmental Impact Statement (EIS). The findings in this report reveal extensive, irreversible harm to our environment, cultural heritage, and public health?harm that cannot be justified or adequately mitigated.

The EIS discloses that dewatering of the Vashon Aquifer could reduce groundwater levels by as much as 30 feet. This would cause up to a 79% reduction in the flow of Sequalitchew Creek, undermining decades of restoration work, eliminating critical salmon habitat, and threatening the long-term ecological health of the creek and its tributaries. Additionally, Edmond Marsh?a Class I wetland?would be virtually eliminated, alongside the destruction of more than 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These actions violate DuPont?s Critical Areas Ordinance and Growth Management policies, which clearly mandate no net loss of wetland and stream functions.

The mitigation measures proposed are both temporary and insufficient. This is not restoration?it is rationalization for environmental degradation.

Impacts to the Nisqually Tribe

Equally disturbing are the cultural ramifications. The Nisqually Tribe has voiced serious concerns regarding the potential desecration of sacred sites and ancestral burial grounds in the project area. Hereditary Chief Leonard Squally has emphasized that these lands have sustained and held cultural meaning for the Nisqually people since time immemorial. Archaeological evidence confirms Indigenous habitation in the region for at least 8,000 to 12,000 years. Disrupting these lands represents not only a loss of cultural heritage but a violation of Indigenous rights and dignity. These concerns are

not speculative?they are supported by formal testimony from the Tribe submitted to the City?s Hearing Examiner.

Threats to Groundwater and Drinking Water

Lowering the water table could also allow saltwater intrusion into freshwater aquifers?especially dangerous in a coastal region?threatening long-term access to clean water. Dewatering would impair natural recharge and filtration processes, degrading water quality and potentially harming private wells and community water systems.

A Blow to Salmon and Orca Recovery

The proposal severely compromises efforts to restore salmon populations in Sequalitchew Creek. Reduced groundwater flows and increased stream temperatures?projected to rise above 21°C in summer?are known to stress or kill salmon, especially during key spawning periods. This not only affects local salmon species such as coho and chum but also the endangered Southern Resident Orca, which relies on healthy salmon runs for survival.

Furthermore, the hydrologic changes would disrupt nearby wetlands?key juvenile rearing grounds for salmon?and diminish the ecological integrity of the Sequalitchew estuary just as planning efforts to reconnect and restore it are beginning. The so-called Sequalitchew Creek Restoration Plan, tied to the mining project, appears more a public relations maneuver than a science-based recovery strategy.

A Climate Catastrophe in the Making

The mine expansion would clear nearly 188 acres of forest and shrubland, eliminating vital carbon sinks and releasing stored CO?. While the EIS minimizes these emissions as a fraction of the state?s total, they are additive to the region?s growing climate burden. Prolonged mining operations?estimated to last an additional 14 years?mean persistent emissions from heavy machinery, transportation, and habitat destruction, further degrading air quality and exacerbating climate impacts.

Wildlife and Biodiversity Loss

The forest and wetland removal would fragment and degrade habitat for vulnerable species such as bats, birds, and the western gray squirrel, contributing to their decline and weakening the biodiversity that supports resilient ecosystems.

## A Threat to Community Health and Recreation

The Sequalitchew Creek Trail is a treasured community space, offering recreation, wildlife observation, and a connection to nature. The proximity of mining operations would erode this experience through increased noise, dust, and loss of natural beauty. The dewatering process also threatens to eliminate the cool groundwater seeps that sustain rare native plants, including the Chain Fern, and enrich the hillside ecosystem.

Increased levels of airborne particulate matter (PM?? and PM?.?) from mining activity pose a serious public health risk, particularly for vulnerable populations such as children, the elderly, and those with respiratory or cardiovascular conditions. Long-term exposure is associated with asthma, heart disease, and neurological disorders.

## Conclusion

In light of the overwhelming environmental, cultural, and public health risks, I urge the City of DuPont and all relevant authorities to reject the proposed mine expansion. There are better, more responsible paths forward?ones that protect our water, forests, and fish, honor Indigenous sovereignty, and preserve the natural spaces that make our community livable and resilient.

This is a pivotal moment. Please act decisively to uphold your commitments to environmental stewardship, cultural respect, and sustainable growth.

*Zip code: 98103*

*Country: US*

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Greetings, Hearing Examiner, I'm Dr Breck Lebegue, retired public health physician, now Co-Chair of the Climate and Health Task Force of WA Physicians for Social Responsibility; and long-term resident of Steilacoom since retiring from JBLM Madigan Med Center. I speak in opposition to expansion of mining operations near Sequalitchew Creek, where I often go for quiet enjoyment of the sights and sounds of the natural environment. 3 points re health:

- Studies show that mining operations based on diesel fuel engines produce PM 2.5 particles that when breathed in, lodge in the lungs, enter the blood and cause lung & heart disease, cancer, even dementia; when accumulated over time. Every little bit hurts our health.
- WA is required by the Climate Commitment Act to decrease greenhouse gases to limit atmospheric warming. Rather than getter cooler, each year is hotter. Fuels make it worse.
- People require outdoor recreation in natural environments for mental health. Anxiety, depression, drug abuse & suicide are increasing. Quiet time in nature heals broken hearts.

For these reasons, I and WPSR urge you to deny the application to expand mining there.

Thank you for doing the right thing for the people of Pierce County and their descendants.

Breck Lebegue MD MPH

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. Hearing Examiner,

There are many and varied critical reasons for you to not allow this project to move forward.

I wish I had time to research federal, state, local laws why this project needs to be stopped; I do not.

I just know that the environmental impact report, the injury to the Nisqually Tribe history and the harm to the 188 acres, the impact on aquifers, water in general, along with destroying wildlife and the human experience of the trail is enough to not allow this project.

Our country is so geared to monetary gains for corporations, without regard to any impacts on nature and humanity that it makes me sick at heart and it is wrong. The almighty dollar should not usurp what is right and just. This Earth, our home, is much more valuable than money!

Thank you

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

*City: Seattle*

*State/Province Abbreviated: WA*

*Zip code: 98117*

*Country: US*

Hearing Examiner,

Thank you for reading my letter. This expansion project has many profound, some irreversible impacts to local wildlife, the Nisqually Tribe, groundwater, and salmon and orca recovery. Our environment should not come at the expense of private profit.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing

Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

My elderly father lives in Edmonds and I visit several times each month. One of my joys is walking and birding at the Edmonds Marsh trail. This small bit of remaining estuary protects many birds and species of birds. The trail always has other walkers enjoying the natural beauty so close a busy commercial and residential district., It would be a shame to approve any project that negatively impacts this habitat.

I join in the paragraphs below

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Hearing Examiner,

We should be doing everything we can to protect the endangered Southern Resident Orcas. Instead, the mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek and adversely affecting salmon habitats. And salmon are the preferred diet of the Orcas. Please consider the environment first!

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Hearing Examiner,

Please see below the reasons I highly disagree with the expansion of the gravel pit. In my opinion it is just not worth the irreversible impact on these vulnerable ecosystems that are slowly vanishing to expand a non essential business in the area.

The location of this mine is too special ecologically to warrant any expansion. I am always in favor of balance. Industrial expansion makes sense in some places and this is not one of them. I work for the railroad so I?m down on the waterfront often where the Sequalitchew and all the small streams and creeks run into the sound. It is a wild area. There are many species still doing well in that area and this expansion will threaten all of that. I see regularly, Bald Eagles, Osprey, Harbor Seal, Harbor Porpoise, Mink, Double Crested Cormorant, Common Loon as well well as many others that thrive eating fish in the brackish freshwater runoffs into the sound. All of this while the mine hums along. A balance that is working, for now. But messing around with this ecosystem could extinguish one of the last undeveloped wild pockets between Nisqually and Point Defiance.

The reason our place in the world is so special is because of the natural wonder and wildness and the proximity of that wildness to our cities. Chipping away at these areas will impact the ecosystem in a way that extinguishes that biodiversity. The gravel pit may provide a few jobs and revenue may go up eventually but there is gravel everywhere. To justify ruining a rare ecosystem to produce a common commodity is absolutely not worth it for 99.9% of people wanting to live around or visit the south sound area.

Thank you for considering my position, as an appreciator of nature as well as an advocate for ethical business expansion, which unfortunately this is not.

Kurtis Messingale

??????????????????-

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Thanks. Patrick casados

Hearing Examiner,

STOP DEWATERING NOW!

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is

closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues,

increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

*Zip code: 98115*

*Country: US*

Hearing Examiner,

Below is the letter that has been suggested I send to you regarding this proposal. I will preface it by saying that it is astonishing to me that, given all that people have learned about climate change, about the importance of the natural environment to our mental health, about the decimation of bird and insect populations in the last 30 years, about the destruction of salmon runs and the detrimental impact on the orca population....all that we've learned about ways to co-exist with other living creatures, to come up with alternatives to raping the land....how can proposals like this even see the light of day?

This proposal is going to extend the life of this gravel mine by FOURTEEN YEARS. Not 50, not 100, not 200. Just FOURTEEN. Are you kidding me? Pioneer Aggregates proposes to obliterate 180 acres of forest, dry up multiple marshes and the water source for Sequalitchew Creek....destruction that would take at least decades to recover from, and which can't actually be "mitigated"....all for FOURTEEN more years?

This is appalling, and I hope the City of Dupont advocates and comes down in favor of the people who live in Dupont and cherish the natural areas of Sequalitchew Creek trail, who are working to see salmon return to the creek and for orca to thrive in Puget Sound.

---

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation

measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assault on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods,

adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning beginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entirety.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This

degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an affront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

I think you know as well as I do that this project will lower the groundwater level and have disastrous consequences to local wetlands. Wetlands are well known as among the most productive habitats for wildlife of all kind. Of course, water is one of the basic elements of life on this planet, and as such it is always necessary for that life. We have eliminated too many wetlands, and global climate change, in particular drought in our region right now, is speeding up the process.

Please pay attention to the EIS and put a halt to any aspect of this project that will harm our wetlands. We can't afford to lose any more of them.

I am an ornithologist, entomologist and ecologist who has studied shorebirds, dragonflies and other wetland animals for my entire adult life.

Hearing Examiner,

Water is Life! Thank you for reading all these emails.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues,

increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like

asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

Hearing Examiner, The consequences of expanding the Pioneer Aggregates South Parcel Mine are so egregious that I can't imagine this being approved; if it were, I can't imagine it surviving court challenges.

John Russell

Seattle

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable

sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately

more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental

disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

*Country: US*

Hearing Examiner,

As a lifelong Tacoma resident, I love my community, and it breaks my heart to see such a damaging proposal even being considered. We need to take serious action to protect our environment, because there?s no replacing it, and fixing it after the damage is done costs us way more than preventing the damage in the first place.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing

Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

I can't believe this is even on the table.  You know that it's probably going to have devastating effects that we aren't expecting.  Please stop letting greedy corporations fleece our town. They'll leave and we'll be left in a dumpy waterless polluted city.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing

Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

I am a military spouse and we have called DuPont home for the last 10 years. As an active duty family, we have lived in many cities but none has been home the way DuPont is. This is mainly due to our natural beauty that we have right in our own backyard. The sequalitchew trail has been a frequent trail to us and I?d say we?ve traveled the trail to the sound hundreds upon hundreds of time. We have explored the trail with the Boy Scouts, cleaned the trail numerous times, done night hikes, taken family and friends for the first time, and with my work in nonprofit work to help military families feel more comfortable in their new duty station.

Taking any part of the trail or surrounding water ways and trees is a travesty. I feel sorry for our future generations and my children?s children of instead of taking the same steps they did as children, they are seeing a gravel pit in its place.

How can anyone be okay with this? And for what? For the almighty dollar. It?s shameful and I could not live with myself if I did not share how much this trail has meant for my military family.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupt salmon habitat and undermine decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

There are several overwhelming reasons to reject this proposal listed below. Know that to approve this would devastate human, plant, and animal quality of life irreparably.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable

sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately

more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning beginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental

disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

As a resident of nearby Lakewood and a recreational hiker, as one who appreciates nature, I am alarmed at the potential damage to Seqalitchew Creek and it surrounding environment. The City of Dupont must do all that it can to protect this important natural resource within its boundaries. the gravel mine expansion does little for the city, while seriously degrading its environmental values. Please do not let this happen.

*Country: US*

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. This is unacceptable. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Dear Hearing Examiner,

On behalf of the Tahoma Bird Alliance, we are writing to voice our strong opposition to the proposed expansion of the CalPortland Gravel Mine. This project presents numerous and alarming threats to the environment, cultural heritage, and community well-being. The points below highlight the most critical concerns, which we urge you to consider in your review process.

Environmental Destruction

The Final Environmental Impact Statement (EIS) reveals catastrophic potential outcomes:

? Threat to Sequalitchew Creek: Dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, resulting in up to 79% loss of the creek's flow. This disruption jeopardizes decades of restoration efforts and salmon habitats.

? Loss of Wetlands and Forests: The expansion threatens Edmond Marsh, a Class I wetland, 170+ acres of forest, and landmark trees. These losses violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions.

Cultural Desecration

The proposed mining activities risk disturbing ancestral graves and sacred sites of the Nisqually Tribe. Hereditary Chief Leonard Squally and the Tribe have raised urgent concerns about protecting this land, which holds immense historical and cultural significance. Allowing such desecration is unconscionable and perpetuates irreversible cultural harm.

Groundwater and Climate Concerns

The project's dewatering activities threaten to salinate the Vashon Aquifer, degrade nearby wetlands, and reduce the natural recharge capacity that protects water quality. Furthermore, clearing 188 acres of forest will not only release stored carbon but also reduce future carbon sequestration, exacerbating climate change.

Threat to Salmon and Orca Recovery

By diminishing Sequalitchew Creek's flow, increasing temperatures, and degrading wetlands, this project directly undermines efforts to rebuild salmon populations. These fish are crucial to the food chain, supporting the endangered Southern Resident Orca. The proposed Sequalitchew Creek Restoration Plan cannot offset the long-term damage caused by the mine.

Impacts on Community and Recreation

The expansion jeopardizes the Sequalitchew Creek Trail, a valued community asset. Noise, air pollution, and habitat loss will degrade the trail's natural ambiance, affecting wildlife observation and recreational enjoyment. Increased particulate matter from mining activities poses serious health risks, particularly for vulnerable populations, and the prolonged operational timeline further amplifies these issues.

Conclusion

The cumulative impacts of this project?environmental degradation, cultural desecration, and community harm?are unacceptable. The proposed mitigation measures are inadequate and fail to address the long-term consequences of the mine's expansion.

On behalf of the Tahoma Bird Alliance, we strongly urge you to reject the expansion of the CalPortland Gravel Mine to protect our water, forests, wildlife, and the cultural and environmental integrity of this cherished region.

Sincerely,

Bruce Morse, Ph.D. Stuart Earley

*Zip code: 98327*

*Country: US*

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Hearing Examiner,

As a citizen of DuPont, I agree with the following statements below and ask to preserve our environment and prevent any damage to it.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable

sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately

more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. As a resident of Dupont, we do not want this in our community. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.
