Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps salt water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of salt water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Hearing Examiner,

You are going to get a lot of these letters. Hopefully you?ll at least read some of them. There?s no reason you can?t stop this now. I return to the area often and this is my favorite place. ?? Don?t succumb to the dollar and loose your soul. It?s not just for today but for generations. No one needs a gravel pit. What you?re getting is shortsighted compared to what you?re giving away.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Don?t ruin the beautiful town of DuPont.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Hearing Examiner,

The Sequalitchew trail is one of the most beautiful places in all of DuPont area. Lovely fauna and flora abound. The trail is just one end of a large network of junction trails in the City, wonderful for walking or biking, and it lets out to a lovely little beach. I have grown up here and walked this trail hundreds and hundreds of times in my life and it is one of the most peaceful public places we have, it deserves to be further untouched. It is also a reminder of some of the very important history of the founding of this town. Please please please reconsider this, there is no need to destroy this wonderful place, I want my kids to be able to have the same love for this beautiful trail and the joy it provides

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

The proposed mining expansion on the South Parcel as outlined in the agreement between the City of DuPont and CalPortland.

While the 2011 settlement agreement outlines phased mining and environmental restoration, several red flags demand deeper scrutiny:

1. Conditional Restoration Risks: The Sequalitchew Creek restoration and groundwater monitoring plans are required before mining the South Parcel. However, restoration is not guaranteed to succeed, and any ecological damage caused by premature dewatering may be irreversible. Once mining begins, the city loses meaningful enforcement leverage.

2. Community Health & Safety Concerns: The South Parcel borders schools, homes, and tribal-interest lands. The risk of silica dust, diesel emissions, and long-term noise pollution puts students, families, and tribal communities at risk.

3. Groundwater Table Threats: The project requires aggressive dewatering to reach mining levels. Aquifer disruption threatens not only Edmond Marsh and Sequalitchew Creek but also long-term hydrological balance.

4. Lack of Tangible Community Benefit: There is no provision for revenue sharing, park development, educational support, or tribal reparations in exchange for the land and environmental risk imposed.

5. Environmental Justice Violations: The proposed expansion may violate the Healthy Environment for All (HEAL) Act by disproportionately impacting sensitive communities. Furthermore, it is unclear if the Nisqually Tribe has been formally consulted in compliance with RCW 43.376.020.

In light of these concerns, I urge the Hearing Examiner and City Council to reject or postpone any further permitting of

the South Parcel until the following occur:

? Independent third-party verification of restoration feasibility

? Full tribal consultation and community referendum

? Environmental impact reevaluation under the HEAL Act framework

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Dear Hearing Examiner,

I oppose the Pioneer Aggregates South Parcel Mine Expansion (PLNG2021-006).

City staff admits this project violates the Comprehensive Plan AND Critical Area Ordinance. The Staff Report states it "does not align with Comprehensive Plan policies" and admits "no mitigation is provided for the significant unavoidable impacts to the surface water bodies" - directly violating DMC 25.105.050, which REQUIRES mitigation "to achieve no net loss of stream function."

Scientists in the Final EIS admit "significant unavoidable adverse impacts" including:

83% creek flow loss along the Sequalitchew Creek trail from drying up natural seeps and springs

Vashon Aquifer levels dropping 8+ feet permanently

Multiple wetlands losing 1-3 feet of water forever

Creek temperatures getting too hot for fish survival

Seep wetlands along the creek ravine disrupted permanently

The EIS states the restoration plan "would likely NOT mitigate these impacts."

The Nisqually Indian Tribe never signed the 2011 Settlement Agreement that underlies this entire project. The sovereign tribal nation is formally appealing the Final EIS, citing:

Failure to properly identify tribal cultural resources

Violation of tribal consultation requirements

No adequate mitigation for impacts to sacred sites

How can you approve a project without consent from the sovereign tribal nation on their ancestral lands?

The city's conditional approval requires 38 conditions to "mitigate" environmental damage that the reports already prove cannot be mitigated. You cannot require the impossible. Plus, CalPortland has had OVER 15 years to provide the mitigation requirements in the Critical Areas Ordinance.

How can you approve a project that:

Violates city law (Comprehensive Plan AND Critical Area Ordinance)

Requires fixing damage scientists say CANNOT be fixed?

Demands impossible mitigation conditions?

This is legally impossible. DENY the approval.

Sincerely,

Karen Konrad

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

*Country: US*

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. Others have listed the tragic and irreversible consequences of allowing this mining. This is the crown jewel of DuPont and as your neighbor I regularly hike here and stop for a meal as do many others. I would be delighted to pay a use fee to park and hike. Save this area. Do whatever else you need to do to preserve and even restore it! Your grandchildren will be proud.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions.

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.
This kind of impact will require mitigation in perpetuity, by CalPortland. Forever.

Because dewatering of the aquifer will potentially impact properties far outside the mining area per the EIS, consent should be required for potentially impacted property owners. Also, a mitigation fund must be established for potentially impacted properties.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations. It also will impact negatively property values for existing homeowners in the draw down area. How much money is being set aside for mitigation to private property owners?

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

Dewatering will require mitigation in perpetuity therefore CalPortland will need to require mitigation forever?in perpetuity. The impacts of development per the EIS will spread out far beyond the mine footprint.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Once mining is complete, open pits will continually fill with water due to the breached aquifer. Cal Portland must provide funding for the dewatering efforts that will be permanently required with respect to the abandoned pits after mining is done.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of DuPont and our entire region.  Reject this proposal. They have lied in the past and will continue doing so. An entire generation has grown up knowing about the threat of mine expansion and threats to the aquifer. Please enter these comments into the record.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner, City and Public,

The Pioneer Aggregates South Parcel Project would endanger and damage our City?s already fragile and tormented ecosystems to a point that recovery is not possible. By allowing this project to proceed we are permanently damaging our natural environment and that of our neighbors. We are in a climate and environmental crisis, doing further harm so that a destructive business can expand is a crime on our land and to our future generations. These wetlands are home to many plant and animal species; they protect our homes from fire risk and give life to an expansion of surrounding ecosystems. Water is our most vital asset, if we choose not to protect it, we are setting our community up for a lifetime of suffering. I am speaking from my heart and through the hearts, health and safety of our future when I urge us to deny this project.

We will not be able to recover the life lost through the deforestation, drainage of our wetlands and aquifers, and lost habitat of our natural neighbors. I am sure that there are other comments being written with all the facts and data to back how I feel. This is a cry for help, a cry that this was never our land to harm, yet there has been so much tragedy, so much loss. How is it ok that still today we allow further destruction? Nature will always fight back, and I would rather be with it, speaking for those who cannot use words to protect themselves, instead of abusing it in the name of corporate profit. Think about what?s good, what?s right, what will our future generations thank us for and what will they hate us for. What side of that line do you want to be on?

There is not just one element at stake but many if we allow this project to proceed; Sequalitchew Creek elimination, Edmonds Marsh elimination, 15 acres of deforestation, 90 landmark trees removed, and an increased fire risk to name some. We already allowed our land to be abused at the cost of warehouses, and business complexes that are left unoccupied. Why would we be so careless to allow so much more life lost. I say this with confidence that this approval would create a moral and environmental deficit that is unrecoverable. We know more than we ever knew before, we are

at and beyond an environmental tipping point and if we allow such crimes against nature to unfold there will be no turning back from our mistakes.  Our willingness to cause harm to the land and burden our future generations is our responsibility to negate.

Please look over the facts and data above corporate profit and unrealistic promise.  Please think of those who can?t speak for themselves and for the future vitality of our community, our environmental region, and for those who cared for this land long before western industry plagued its beautiful natural function. The future is in how we work with the land instead of tearing it apart. Our responsibility is in what we choose to do in this moment.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Hearing Examiner,

As each year passes, industry grows, and more carbon is pumped into the atmosphere our winters shorten and our glaciers shrink. For many communities, including large cities such as Tacoma, water which would normally come from upstream dams, is being needed more and more from underground aquifers during the hot summer months.

If we think 10 years into the future, how are those needs going to expand further? Will cities like Tacoma need to be pumping in water from nearby aquifers like those in DuPont? As we?ve seen in California, water is pumped hundreds of miles during droughts, and Washington doesn?t seem far off.

10 years from now, what will be the actual benefit of this gravel mine? Will any benefits outlast the long-standing impacts to critical groundwater?

And what about the impacts to Salmon? On air quality? How much money will have to be spent cleaning up this mess once the jig is up?

What I?m encouraging is proactive thinking. Think generations on. What is best, healthiest, most beneficial to DuPont residents not just now, but 10, 20, 50 years from now?

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. Hearing Examiner,

Hi. You might see a lot of letters like this, and for good reason; the following (after the double forward-slash, //) is a clear and concise summary of the FEIS for the Pioneer Aggregates South Parcel Project and the impacts it would have on our community, big and small. But if I were in your shoes, I'd want to see people actually talk about it, so here I am doing so.

Reading the FEIS, I ask myself nuanced questions to determine if I am in favor or in opposition of the expansion of a nearby gravel mine. "Who does this benefit? Who does this harm? What will this change now? What will this change in the future?" alongside the "How?" and "Why?"s to further understanding of cause and effect.

I believe this proposal benefits CalPortland's bottom line by receiving funding in exchange for construction equipment, materials, and services. I believe this proposal likely benefits the city of DuPont and its officials, who would gain the tax revenue of goods and services involved in the expansion of the mine. But due to the evidence shown in the FEIS, this is not a sustainable or worth-while benefit.

I believe this proposal will harm our community by straining our relationship with tribes like Nisqually (who have lived in these lands and have intimate knowledge of them), exposing our vulnerable populations to pollution, and destroying the rare and natural beauty we enjoy in our environment. I believe this proposal will harm our ecosystem's wildlife through the destruction of habitats, the constricting of creek flow, and the stressing of its salmon to spawn, a keystone species that this ecosystem depends on to exist. I believe this proposal could even harm local governments like DuPont if it at any point tries to heal the harm done to us, as the cost of repairs and public services would come straight from the taxes it tried to garner and maintain.

But the logic we hold in opposition of this proposal of expansion is not as complicated. It includes a simple question:

which of our options is best for us? Not just the county, or the people, or the wildlife, but every single living, breathing thing on this Earth. Such an option shows worthwhile consideration of this. The expansion of a gravel mine in our community is not such an option.

Thank you. Please enter these comments into the record.

The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Most Esteemed Hearing Examiner:

I am a resident of Pierce County, and I have walked along the Sequalitchew Creek Trail and a little stretch of the beach at least once per year. It is a family friendly walk, not overstrenuous, but rewarding. I love to see the natural conservation areas. It is the only reason I have ever visited Dupont.

I am afraid that the Final Environmental Impact Statement regarding the Pioneer Aggregates South Parcel Project reveals alarming consequences for the Sequalitchew Creek. The Vashon Aquifer's groundwater levels could be reduced by up to 30 feet, resulting in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts.

Lower groundwater inputs cresult in higher stream temperatures. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that will negatively impact salmon populations such as coho and chum salmon, as well as cutthroat trout. This is not all. The expansion threatens elimination of Edmond Marsh, a Class I wetland, and 10.8 acres of the Kettle Wetland. It could very well destroy over 170 acres of forest, and at least 90 landmark trees.

These negative impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

The Sequalitchew Creek "Restoration Plan" proposes to mitigate some impacts of the mining project. It is putting a band-aid on a limb that is bleeding out while falsely taking credit for having saved it. It is mere lip service, intended to placate the public who won't take action until it is too late. Of course, a more robust and accurate restoration plan can

and should be created and funded without dependency on the gravel mine.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions that are both direct and indirect from machinery and vehicles. Consider the noise and light pollution too. The ongoing habitat disruption will have long-term ecological and climatic effects, such as a decline in the population of local bats, birds, and the western gray squirrel, for example. It also threatens the health, safety and enjoyment of frequent visitors to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington. Local residents should also be alarmed by the exposure to increased particulate matter. Anyone with pre-existing respiratory problems and cardiovascular diseases will be at increased risk.

The Nisqually Tribe's Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas. The Nisqually Tribe has submitted formal comments to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites. It is our duty to safeguard their cultural heritage and its link to the land and water.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Protect the people and the habitat enjoyed by many species. Reject this proposal.

Please enter these comments into the record. Thank you.

*City: Lakewood*

*State/Province Abbreviated: WA*

*Zip code: 98499*

*Country: US*

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

# Letter from: Garry Oak  Coalition

*City: Lakewood*

*State/Province Abbreviated: WA*

*Zip code: 98499-1934*

*Country: US*

Hearing Examiner,

I am writing on behalf of the Garry Oak Coalition, an environmental non-profit based in Lakewood, Washington. We are profoundly concerned about the clearly foreseeable adverse environmental impacts were this project to proceed.

Please make our non-profit a party of record and inform us of any decisions or future comment deadlines.

No meaningful mitigation is possible for the dewatering of our sole source aquifer, which is a resource of critical importance, especially considering the water crisis we find ourselves in. Our glaciers are disappearing and our rainfall is less, and droughts longer.

Dewatering, because it would severely reduce the water supply to Sequalitchew Creek, would also have a clearly foreseeable impact on the viability of Sequalitchew Creek as salmon habitat. Salmon are a keystone species for our region, which means they support the entire ecosystem. As such, they are also of fundamental cultural importance to the native peoples here.

Best available science requires the protection of the aquifer and of the salmon. Dupont is subject to the Growth Management Act's requirements, including adhering to best available science in its decision-making. By allowing the destruction of critical areas (aquifer, salmon habitat and other priority habitat, including Garry oaks) without meaningful mitigation, which in the case of the aquifer does not exist, Dupont will have a net loss of critical areas, which is forbidden under the GMA.

The time is now to protect our aquifer -- because our lives and the lives of future generations of all living beings, depend on it.

Sincerely,

Christina Manetti, Ph.D.

Garry Oak Coalition

Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Hearing Examiner,

This is about money, corruption and greed. Taking this from the community would be devastating for all involved. This land is the people's land to learn, enjoy and use. We will never forget how it was taken and will watch the mine slowly destroying its beauty. This will enrage the community for years to come. There will be no winners and will end in regret for everyone. Please make this decision in good faith.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Hearing Examiner,

The Final Environmental Impact Statement reveals devastating consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

I beg of you to please consider all the effects upon our world, our community and our history.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

I realize this is a form letter and you are getting a lot of them. I was incredibly disappointed to see this is still a possibility. It feels so short sighted in a time when we need to protect what few natural resources we haven?t damaged. I walk the trail often with my child and dog. I always see a handful of people if it?s odd hours or raining, and dozens of people if it?s sunny or typical walking hours. It is a gem that is listed on all trails and Washington trails association. It brings people from out of area to Dupont who likely frequent the businesses on their way through.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Hearing Examiner,

I grew up in this neighborhood and know how beautiful and important it is to the local community!

Below are some of the many reasons this project should NOT be allowed to happen!

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

As the population in our area increases, it seems unconsciounable that you would allow destruction of aquifers, forest lands etc in favor of corporate interests.

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.

Indirect Emissions: Resulting from electricity consumption and the production of materials used in operations.

While the Environmental Impact Statement (EIS) acknowledges that these emissions would constitute a small percentage of the state's total GHG inventory, they are nonetheless additive and contribute to cumulative climate impacts.

The expansion entails clearing approximately 188 acres of previously undisturbed forest and shrubland. This vegetation currently acts as a carbon sink, absorbing CO? from the atmosphere. Its removal not only releases stored carbon but also diminishes the area's future carbon sequestration capacity.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained emissions from machinery and vehicles, as well as ongoing habitat disruption, which can have long-term ecological and climatic effects.

When combined with other regional developments and industrial activities, the project's emissions and environmental disturbances contribute to broader cumulative climate impacts. These include exacerbated local air quality issues, increased regional temperatures, and strain on local ecosystems already vulnerable to climate change.

The mine expansion threatens to degrade and fragment critical habitats for bats, birds, and the western gray squirrel, leading to declines in these wildlife populations.

A Threat to Community and Recreation

The proposed expansion of the Pioneer Aggregates South Parcel Project poses significant threats to the Sequalitchew Creek Trail, a cherished recreational asset in DuPont, Washington.

The expansion would bring mining operations closer to the trail, leading to increased noise and visual disruptions. The construction of a 20-foot-high berm on the south side of Phase 2C is planned to mitigate noise, but the proximity of mining activities may still detract from the trail's natural ambiance.

Dewatering activities associated with the mine could lower groundwater levels, affecting the flow of Sequalitchew Creek. Frequent trail walkers will notice the groundwater seeps that sustain the lush hillside, including a rare native Chain Fern, that grows out of this specific habitat. De-watering would eliminate these cool-water seeps likely in their entireity.

The removal of forested areas and wetlands for mining will lead to habitat loss for various wildlife species. This degradation may reduce opportunities for wildlife observation along the trail, impacting the experience for nature enthusiasts.

The project is anticipated to extend mining activities by approximately 14 years. This prolonged period of operation means sustained disturbances, potentially affecting trail accessibility and enjoyment over a significant timeframe while increasing localized air pollution and heat island affects.

The mining activities are expected to elevate levels of particulate matter (PM), particularly PM?? and PM?.?, due to operations such as excavation, blasting, and transportation. These fine particles can travel long distances, affecting air quality in surrounding communities.

Exposure to elevated levels of particulate matter is linked to various health issues:

Respiratory Problems: Inhalation of fine particles can lead to reduced lung function and exacerbate conditions like asthma and chronic bronchitis.

Cardiovascular Diseases: Air pollution contributes to heart diseases and can increase the risk of heart attacks and strokes.

Neurological Effects: Long-term exposure has been associated with cognitive decline and neurological disorders.

Vulnerable Populations: Children, the elderly, and individuals with pre-existing health conditions are particularly susceptible to the adverse effects of air pollution.

The applicant's relentless pursuit of profit in plundering this archeologically and ecologically unique landscape is an afront to the residents of Dupont and our entire region.  Reject this proposal. Please enter these comments into the record.

Hearing Examiner,

The Final Environmental Impact Statement reveals alarming consequences: dewatering the Vashon Aquifer could reduce groundwater levels by up to 30 feet, threatening the health of Sequalitchew Creek. This would result in the loss of up to 79% of the creek's flow, disrupting salmon habitat and undermining decades of restoration efforts. Additionally, the expansion threatens to eliminate Edmond Marsh, a Class I wetland, and destroy over 170 acres of forest, 10.8 acres of the Kettle Wetland, and at least 90 landmark trees. These impacts violate DuPont?s Critical Area Ordinance and Growth Management policies, which mandate no net loss of wetland and stream functions. The proposed mitigation measures are insufficient and temporary, leaving the environment vulnerable in the long term.

Impacts to the Nisqually Tribe

The Nisqually Tribe has expressed concerns about the potential desecration of ancestral graves and sacred sites within this landscape. Hereditary Chief Leonard Squally has highlighted the importance of protecting these areas, which have sustained the Nisqually people since time immemorial. The proposed mining activities pose risks of disturbing these sacred sites, leading to irreversible cultural losses. The Nisqually people have inhabited the Sequalitchew area since time immemorial, with archaeological evidence indicating human presence in the broader Puget Sound region for at least 8,000 to 12,000 years.

The Nisqually Tribe's concerns are substantiated by their formal comments submitted to the City of DuPont's Hearing Examiner, emphasizing the adverse impacts on cultural resources and urging for the protection of these irreplaceable sites.

In light of these considerations, it is imperative to oppose the proposed mine expansion to safeguard the cultural

heritage and environmental integrity of the Nisqually Tribe.

Threat to Groundwater

Lowering the groundwater table can reduce the pressure that keeps saline water from encroaching into freshwater aquifers, especially in coastal areas. If the Vashon Aquifer experiences significant drawdown, it could potentially allow for the upward movement of saline water from deeper layers or lateral intrusion from nearby saline sources, leading to salination of the aquifer.

Moreover, dewatering could impact nearby wetlands and marshes, such as Edmond Marsh, by lowering groundwater levels, which may lead to ecological degradation. The loss of these wetlands could further alter the natural recharge and filtration processes that protect aquifer water quality.

An Assualt on Salmon and Orca Recovery

The mining project's dewatering activities are expected to lower groundwater levels, diminishing the flow from springs that currently feed Sequalitchew Creek. This reduction will lead to decreased streamflow, particularly during dry periods, adversely affecting salmon habitats. The Final Environmental Impact Statement (EIS) notes that "the contribution from springs with the Proposed Action and Sequalitchew Creek Restoration Plan would be lower than under existing conditions," potentially impacting fish migration and spawning.

Lower groundwater inputs can result in higher stream temperatures, which are detrimental to salmon, especially during summer months. The EIS anticipates that "creek temperatures in the summer?particularly June through August?are expected to rise to 21°C," a level that can stress salmon populations.

Changes in groundwater levels are expected to alter the hydrology of nearby wetlands, such as Edmond Marsh, which serve as critical rearing habitats for juvenile salmon. Disruptions to these wetlands could impair their ability to support salmon life stages.

The Sequalitchew Creek Restoration Plan is proposed to mitigate some impacts of the mining project, but it is ultimately more of a re-engineering plan designed to foil public outcry over the destruction of so much habitat. Its implementation is closely tied to the mining proposal, raising concerns about potential delays or dependencies that could hinder timely restoration efforts. Most importantly, a more robust and accurate restoration plan could be created and funded without

dependency on the gravel mine.

The combined effects of reduced streamflow, increased temperatures, and altered habitats could cumulatively impact salmonid species, including coho and chum salmon, as well as cutthroat trout. These species rely on specific habitat conditions that may be compromised by the proposed mining activities. With planning begginning to allow the Sequalitchew estuary to flow freely and rebuild, this project is in direct contradiction. Salmon are a vital food source for the endangered Southern Resident Orca, and the Sequalitchew system once supported thousands of fish. This project would greatly impair our ability to rebuild this break in the food chain.

A Climate Catastrophe

The project's expansion would lead to both direct and indirect GHG emissions

Direct Emissions: Arising from on-site activities such as excavation, processing, and transportation of materials.
